Disclaimer Notice

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgment when deciding the most appropriate care to enrollees. The CDPHP coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

Background

Alzheimer's disease (AD) is a fatal degenerative brain disease characterized by progressive loss of cognitive skills such as such as memory, language, navigation, problem-solving, and physical function. The hallmark of AD is the progressive accumulation of beta-amyloid protein plaques and neurofibrillary tangles of hyperphosphorylated tau protein in the brain; these are hypothesized to lead to damage and eventual death of neurons over decades.[1]

Lecanemab

Leqembi (lecanemab-irmb) is a humanized immunoglobulin gamma 1 (IgG1) monoclonal antibody directed against aggregated soluble and insoluble forms of amyloid beta. It was the second anti-amyloid agent approved under the accelerated pathway. Approval was based on data from the Phase 2 double-blind, placebo-controlled, parallel-group, dose-finding study (Study 201) of 856 patients. Patients receiving the treatment had significant dose- and time-dependent reduction of amyloid beta plaque, with patients receiving the approved dose of lecanemab, 10 mg/kg every two weeks, having a statistically significant reduction in brain amyloid plaque from baseline to Week 79 compared to the placebo arm, which had no reduction of amyloid beta plaque.

Data from the Phase 3 CLARITY AD trial were published in early January 2023. Clarity AD was an 18-month, multicenter, double blind, placebo-controlled, parallel-group trial involving persons with mild cognitive impairment due to Alzheimer's or mild Alzheimer's disease-related dementia ages 50-90. 1795 participants underwent randomization 1:1 to receive lecanemab 10 mg/kg every two weeks or placebo. The mean Clinical Dementia Rating–Sum of Boxes (CDR-SB) score at baseline was approximately 3.2 in both groups. The adjusted least-squares mean change from baseline at 18 months was 1.21 with lecanemab and 1.66 with placebo (difference, −0.45; 95% confidence interval [CI], −0.67 to −0.23; P<0.001). Lecanemab showed a 27% reduction in clinical decline compared to placebo at 18 months (a 0.45-point difference on the CDR-SB score. Lecanemab resulted in infusion-related reactions in 26.4% of the participants and amyloid-related imaging abnormalities (ARIA) with edema or effusions in 12.6%. 17.3% of participants in the lecanemab group experienced ARIA with microhemorrhages or hemosiderin deposits.

The Institute for Clinical and Economic Review (ICER) published its evidence report on lecanemab for Alzheimer's Disease April 2023. ICER's report concluded that significant uncertainties remain as to whether the average benefits of lecanemab will exceed its risks. A majority of the California Technology Assessment Forum was unconvinced that the current evidence adequately demonstrates lecanemab provides a net benefit to patients. They remained uncertain that amyloid removal is an appropriate surrogate outcome for clinical benefit and instead look to the clinical outcomes found in randomized trials. However, there is disagreement among experts about the clinical meaningfulness of the magnitude of change in CDR-SB in the lecanemab trial. ICER also remained concerned real world ARIA occurrences and consequences may be more severe if monitoring MRIs are not as frequent as in the clinical trial, the population treated differs from the trial population, and clinicians are less expert than those who participated in the randomized trial. **In aggregate, the net health benefits of lecanemab in patients with early AD may be small or even substantial, but there remains a possibility of net harm from ARIA**. ICER rated treatment with lecanemab in MCI due to AD or mild AD as "Promising but Inconclusive" (P/I). For adults with early Alzheimer's disease (i.e., Mild Cognitive Impairment due to Alzheimer's disease and mild Alzheimer's dementia), a **majority of panelists (12-3) found that current evidence is not adequate to demonstrate a net health benefit of lecanemab when compared to supportive care alone**.

ICER also noted concerns with different populations from the CLARITY-AD trial. The subgroup analysis of CLARITY-AD data suggests that there may be lower efficacy of lecanemab in ApoE ε4 homozygotes, as well as higher risk of ARIA. ARIA-E occurred more frequently in ApoE ε4 carriers compared to non-carriers in the lecanemab treated group (3.4% vs 1.4%), and also occurred more in ApoE ε4 homozygotes compared to heterozygotes (9.2% vs 1.7%). Like ARIA-E, ARIA-H occurred more frequently in ApoE ε4 carriers compared with non-carriers (19.7% versus 11.9% in the lecanemab treated group) and was more frequent in ApoE ε4 homozygotes compared to heterozygotes (39% versus 14%).

Leqembi was initially approved January 6, 2023, under the Accelerated Approval pathway. Following approval in January, there was petition from the Alzheimer's Association to provide wider coverage for Leqembi on Medicare. CMS rejected the petition, thus upholding coverage would only be for those in clinical trials under the national coverage determination. As of July 6, 2023, Medicare more broadly covers Leqembi under the NCD issued April 7, 2022, as Leqembi was granted traditional approval by the FDA. Per the CMS statement on July 6.

2023, to receive Medicare coverage, patients will need to: 1) be enrolled in Medicare, 2) be diagnosed with mild cognitive impairment or mild Alzheimer's disease dementia, with documented evidence of beta-amyloid plaque on the brain, and 3) have a physician who participates in a qualifying registry with an appropriate clinical team and follow-up care. The registry is available at: https://qualitynet.cms.gov/alzheimers-ced-registry.

Donanemab

Kisunla (donanemab-azbt) is a humanized immunoglobulin gamma 1 (IgG1) monoclonal antibody directed against insoluble Ntruncated pyroglutamate amyloid beta. The FDA had issued a CRL for the accelerated approval of donanemab in January 2023 due to the limited number of patients with at least 12 months of drug exposure data provided in the submission. However, Kisunla is now the third FDA-approved anti-amyloid therapy, approved on July 2, 2024. Approval of Kisunla was based on results from the Phase 3 TRAILBLAZER-ALZ-2 study and the TRAILBLAZER-ALZ program. In TRAILBLAZER-ALZ-2, Kisunla was evaluated in 1736 participants with early symptomatic AD (MCI or mild dementia due to AD) and the presence of confirmed AD neuropathology. Participants were randomized in a 1:1 ratio to receive donanemab (n = 860) or placebo (n = 876) intravenously every 4 weeks for 72 weeks. 1320 (76%) patients completed the trial. At 76 weeks, least-squares mean differences favored treatment by 3.25 points on the integrated Alzheimer's Disease Rating Scale (iADRS) in the low/medium tau group (35.1% slowing of disease progression) and 2.92 points in the overall population (22.3% slowing). 76.4% of patients in the donanemab group showed complete plaque clearance on PET at 76 weeks.

The incidence of serious adverse events in TRAILBLAZER-ALZ 2 was 17.4% in the donanemab group and 15.8% in the placebo group. Either ARIA-E or ARIA-H occurred in 314 participants (36.8%) receiving donanemab and 130 (14.9%) receiving placebo. ARIA-E occurred in 205 participants (24.0%) in the donanemab group and in 18 (2.1%) in the placebo group. The incidence of ARIA-H was higher in the donanemab group than the placebo group (268 participants [31.4%] vs 119 participants [13.6%]). The incidence of microhemorrhage and superficial siderosis was greater in the donanemab group than in the placebo group (microhemorrhage: 26.8% vs 12.5%; superficial siderosis: 15.7% vs 3.0%). Notably, in the TRAILBLAZER-ALZ 2 study, the incidence of serious ARIA was 1.6%, including two participants whose death was attributed to ARIA and a third participant who died after an incident of serious ARIA. Infusion-related reactions occurred in 8.7% of participants with most cases mild to moderate in severity.

Summary	
Effective Date of Policy:	3/10/2026
Indications	Treatment of Alzheimer's disease. Treatment with should be initiated in patients with mild cognitive impairment or mild dementia stage of disease, the population in which treatment was initiated in clinical trials
ICD10 Diagnosis Codes	G30 Alzheimer's Disease
HCPCS code	Leqembi: J0174 Kisunla: J0175
Availability	Leqembi: 500 mg/5 mL (100 mg/mL) single-dose vial, 200 mg/2 mL (100 mg/mL) single-dose vial, 360 mg/1.8 mL (200 mg/mL) single-dose prefilled autoinjector Kisunla: 350 mg/20 mL (17.5 mg/mL) single-dose vial
Duration	Initial: 6 months Continuation: 6 months

Medicare reviews are to follow the national coverage determination (NCD) issued by CMS effective 12/12/2022. The NCD can be found on the CMS website at:
https://www.cms.gov/medicare-coverage-database/view/ncd.aspx?ncdid=375&ncdver=1

Considerations

- Prior authorization is obtained through the CDPHP pharmacy department.
- CDPHP reserves the right to make decisions based on clinical judgment on a case-by-case basis.
- For Leqembi:
  - Member is having follow up MRI scans to rule out acute or sub-acute micro or macrohemorrhage prior to the 5th, 7th, and 14th infusions
  - After 18 months, can continue treatment once every 2 weeks IV or transition to an every 4 week intravenous or weekly subcutaneous maintenance dosage
- For Kisunla: Member is having follow up MRI scans to rule out acute or sub-acute micro or macrohemorrhage prior to the 2nd, 3rd, 4th, and 7th infusions

Pharmacy Policy

Policy/Procedure Name:	**Control Number:**
MEDICAL INJECTABLE DRUGS REQUIRING PRIOR AUTHORIZATION	**1350/20.000283**

DISCLAIMER NOTICE:

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgment when deciding the most appropriate care for enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services.

EFFECTIVE DATE OF POLICY: 1/1/2026

DESCRIPTION: CDPHP requires prior authorization for certain medical injectable drugs before they will be approved for coverage. This applies to drugs being administered in a physician's office or another medical setting when the claim is submitted on an HCFA 1500 for payment in Facets.

APPLICATION

- Coverage will be approved when specific approval criteria for the requested drug are met, according to CDPHP policies in effect.
- If there is not a CDPHP policy in effect that describes the criteria for prior-authorization approval, prior authorization will be reviewed using the Local Coverage Determination (LCD) for Drugs and Biologicals, Coverage of, for Label and Off-Label Uses (L33394). The LCD can be found on the CMS website at: https://www.cms.gov/medicare-coverage-database/view/lcd.aspx?lcdid=33394&ver=54&=
- Testopel is billed with code S0189 and will require PA review. Testopel will be approved only for FDA-approved, Medicare-covered indications. It will not be covered for off-label use of erectile dysfunction, since this is not a Medicare-covered indication.

POLICY CONSIDERATION(S): The most up-to-date list of drugs requiring prior authorization, as well as the prior-authorization criteria, can be found on the CDPHP Medical Benefit Formulary and Medicare Advantage Prior Authorization Criteria documents for enrollees and practitioners on the CDPHP secure interfaces at https://www.cdphp.com.

MEDICARE ADVANTAGE: Subject to the terms and conditions noted in above application. Benefits for Medicare Part D prescription drugs are available only to enrollees who have elected a CDPHP Medicare Advantage plan. The CDPHP Medicare Advantage plan products do not cover any prescription drugs not covered by Medicare, with the exception of additional coverage purchased with a group-enhanced rider. In addition, for those individuals enrolled in the CDPHP Medicare Advantage product who have not elected a Part D option, CDPHP covers only those prescription drugs covered by Medicare Parts A and B, not those covered by Part D. Coverage is available for any eligible Part D drug prescribed for a medically accepted indication as cited in one or more of the following references: American Hospital Formulary Service Drug Information; United States Pharmacopeia Drug Information, or its successor; and DrugDex Information System. Coverage is available for any eligible Part D drug and biological used off-label in an anti-cancer chemotherapeutic regimen for a medically accepted indication as cited in one or more of the following references: American Hospital Formulary Service Drug Information; United States Pharmacopeia Drug Information, or its successor; DrugDex Information System; National Comprehensive Cancer Network (NCCN) Drugs and Biologics Compendium; Clinical Pharmacology; and Wolters Kluwer Lexi-Drugs (Lexicomp). In addition, for Part D drugs used in anticancer chemotherapy regimens, coverage for additional off-label use may be available if scientific literature approved by the secretary of health and human services supports such use.

This Pharmacy Policy is the exclusive property of Capital District Physicians' Health Plan, Inc. (CDPHP®) and its affiliated companies, CDPHP Universal Benefits,® Inc. (CDPHP UBI) and Capital District Physicians' Healthcare Network, Inc. (CDPHN). The contents and form of this policy are proprietary to CDPHP. Any reproduction or replication of this policy without the express written permission of CDPHP, CDPHP UBI, and CDPHN is strictly prohibited. This policy is subject to contractual limitations and/or parameters established in any Employer-sponsored Summary Plan Description (SPD) and/or Benefit Design Document (BDD).

Disclaimer Notice

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of a beneficiary's individual benefit plan.

If there is a discrepancy between this policy and a beneficiary's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgment when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

Effective: 1/1/2026

Background

This document provides an overview of outpatient prescription drug coverage policies under Medicare. Beneficiaries who are inpatients of hospitals or skilled nursing facilities (SNF) during covered stays may receive drugs as part of their treatment. Typically, the payment for drugs is bundled into the Medicare Part A payments made to these types of facilities. Under the hospice benefit, beneficiaries receive drugs that are medically necessary for symptom control or for pain relief.

Part B Medications/Drugs

In general, references are seen to five major categories of Medicare Part B drug spending: 1. Drugs billed by physicians and typically provided in physicians' offices (such as chemotherapy drugs); 2. Drugs billed by pharmacy suppliers and administered through durable medical equipment (DME), such as respiratory drugs given through a nebulizer; 3. Drugs billed by pharmacy suppliers and self-administered by the patient (such as immunosuppressive drugs and some oral anti-cancer drugs); 4. Separately billable drugs provided in hospital outpatient departments; and 5. Separately billable End Stage Renal Disease (ESRD) drugs such as erythropoietin (EPO). Regional differences in Part B coverage policies for drugs can occur in the absence of a national coverage decision. A drug for which coverage is available under Part A or Part B, as it is being "prescribed and dispensed or administered" with respect to the individual, is excluded from the definition of a Part D drug and, therefore, cannot be included in Part D basic coverage.

Traditional Medicare (Part A/B) does not cover most outpatient prescription drugs. Medicare bundled payments made to hospitals and skilled nursing facilities generally cover all drugs provided during a stay. Medicare also makes payments to physicians for drug or biological products that are not usually self-administered (see definitions). This means that coverage is usually limited to drugs or biological products administered by infusion or injection. However, if the injection is generally self-administered (e.g., Imitrex), it is not covered.

For detailed coverage criteria for medications/drugs under Part B, refer to the Medicare Benefit Policy Manual, Chapter 15, Section 50- Drugs and Biologics.

Part B Covered Drugs in the Context of a Professional Service

Drugs furnished "incident to" a Physician's Service: These are injectable or intravenous drugs that are administered predominantly by a physician or under a physician's direct supervision as "incident to" a physician's professional service. The statute limits coverage to drugs that are not usually self-administered. In order to meet all the general requirements for coverage under the "incident to" provision, an FDA approved drug or biological product must:

- Be of a form that is not usually self-administered (as determined by the A/B MAC contractor-click here for exclusion list*);
- Must be furnished by a physician; and
- Must be administered by the physician, or by auxiliary personnel employed by the physician and under the physician's personal supervision.

The charge, if any, for the drug or biological product must be included in the physician's bill and the cost of the drug or biological product must represent an expense to the physician. Drug and biological products furnished by other health professionals may also meet these requirements.

**Note as of 10/15/2021 Stelara has been added to the self-administered drug exclusion list (A53021). This means that the Part B MAC (NGS) has determined that more than 50% of all use is self-administered and claims will no longer be paid under Part B with a J code J3357. Claims will need to be submitted through the pharmacy Part D benefit.*

Relationship between Part B and Part D Coverage	Categories of Separately Billable Part B Drugs	Comments
The same drug dispensed by a **pharmacy** is covered under Part B if provided as part of a service in a provider setting, physician's office, or home.	1.Drugs furnished "incident to" a physician service 2. Separately billable ESRD drugs 3. Separately billable drugs in Hospital Outpatient Departments (HOPDs) 4. Separately billable drugs in Comprehensive Outpatient Rehabilitation Services (CORFs) 5. Drugs packaged under the Outpatient Prospective Payment System (OPPS) 6. Drugs furnished by ESRD facilities and included in Medicare's ESRD composite rate 7. Osteoporosis drugs provided by home health agencies under certain conditions 8. Drugs furnished by Critical Access Hospitals (CAHs) outpatient departments 9. Drugs furnished by Rural Health Clinics (RHCs) 10. Drugs furnished by Federally Qualified Health Centers (FQHCs) 11. Drugs furnished by Community Health Centers (CMHCs) 12. Drugs furnished by ambulances.	*Generally, if a beneficiary presents at a pharmacy with a script, it would be a Part D drug*. The availability of Part B coverage in a provider setting or physician's office should not result in a refusal of coverage under Part D for drugs dispensed by a pharmacy. This is the case because coverage is not available under Part B as the drug is being "prescribed and dispensed or administered" with respect to the individual. Thus, for example, while Part B covers certain injectables provided "incident to" a physician services, injectables dispensed by a pharmacy are not being "furnished" by a physician and would be Part D drugs. Part D sponsors should deny claims submitted by members for Part B-covered injectables if they are administered in a physician office from a physician's supply. Part D sponsors can subject injectables and infusables that would be covered under Part B as "incident to" a physician service, to a prior authorization program. To the extent that the sponsor determines based on medical literature that there exist serious safety concerns such that it would go against accepted medical practice for a particular injectable or infusible to be dispensed directly to an enrollee, the claim can be denied as not "reasonable." Safety-based reasonableness determinations will need to be made on a case-by-case basis, since circumstances will vary**. In general, however, there are very few instances when an injectable or infusible drug could not be reasonably dispensed directly to the patient.**

Part D Medications/Drugs

Definition of a Part D Covered Drug (see also Medicare Prescription Drug Benefit Manual, Chapter 6, Section 10- Definition of Part D Drugs).

A Part D covered drug is available only by prescription, approved by the FDA (or is a drug described under section 1927(k)(2)(A)(ii) or (iii) of the Act), used and sold in the United States, and used for a medically accepted indication (as defined in section 1927(k)(6) of the Act). In addition, for the applicable drugs of a manufacturer to be covered under Part D, the manufacturer must participate in the Manufacturer Discount Program (see Participating Manufacturers here).

A covered Part D drug includes prescription drugs, biological products, insulin as described in specified paragraphs of section 1927(k) of the Act, vaccines licensed under section 351 of the Public Health Service Act and for vaccine administration on or after January 1, 2008, its administration. The definition also includes medical supplies directly associated with delivering insulin to the body, including syringes, needles, alcohol swabs, gauze, and insulin injection delivery devices not otherwise covered under Medicare Part B, such as insulin pens, pen supplies, and needle-free syringes, can satisfy the definition of a Part D drug. CMS defines those medical supplies to include syringes, needles, alcohol swabs, gauze, and those supplies directly associated with delivering insulin into the body.

Part D Excluded Drugs
The definition of a covered Part D drug specifically excludes drugs or classes of drugs, or their medical uses, which may be excluded from coverage or otherwise restricted under Medicaid under section 1927(d)(2) of the Act, with the exception of smoking cessation agents. The drugs or classes of drugs that may currently be otherwise restricted under Medicaid include:
• Agents when used for anorexia, weight loss, or weight gain (even if used for a non-cosmetic purpose (i.e., morbid obesity).
• Agents when used to promote fertility.
• Agents when used for cosmetic purposes or hair growth.
• Agents when used for the symptomatic relief of cough and colds.
• Prescription vitamins and mineral products, except prenatal vitamins and fluoride preparations.
• Nonprescription drugs.
• Covered outpatient drugs which the manufacturer seeks to require as a condition of sale that associated tests or monitoring services be purchased exclusively from the manufacturer or its designee.
• Agents when used for the treatment of sexual or erectile dysfunction (ED). ED drugs will meet the definition of a Part D drug when prescribed for medically-accepted indications approved by the FDA other than sexual or erectile dysfunction such as pulmonary hypertension. **However, ED drugs will not meet the definition of a Part D drug when used off label, even when the off-label use is listed in one of the compendia found in section** 1927(g)(1)(B)(i) of the Act**: American Hospital Formulary Service Drug Information, and DRUGDEX® Information System. ED drugs meet the definition of a Part D drug only when used for FDA-approved indications.**

Drugs Not Excluded from Part D Coverage
• Prescription drug products that otherwise satisfy the definition of a Part D drug are Part D drugs when used for AIDS wasting and cachexia due to a chronic disease, if these conditions are medically-accepted indications as defined by section 1927(k)(6) of the Act for the particular Part D drug. Specifically, CMS does not consider such prescription drug products being used to treat AIDS wasting and cachexia due to a chronic disease as either agents used for weight gain or agents used for cosmetic purposes.
• Part D drugs indicated for the treatment of psoriasis, acne, rosacea, or vitiligo are not considered cosmetic.
• Vitamin D analogs such as calcitriol, doxercalciferol, *and* paricalcitol when used for a medically-accepted indication as defined by section 1927(k)(6) of the Act, are not excluded because CMS interprets the exclusion of prescription vitamin D products as being limited to products consisting of ergocalciferol (vitamin D2) and/or cholecalciferol (vitamin D3).
• Prescription-only smoking cessation products.
• Prescription Niacin products (Niaspan, Niacor).
• Cough and cold medications are eligible to meet the definition of a Part D drug in clinically relevant situations other than those of symptomatic relief of cough and*/or* colds. For example, when *"*cough*"* medications are used *to treat a medical condition that causes a cough, such as the use of bronchodilators for the treatment of bronchospasm in asthma, CMS does not consider these "cough" medications as excluded drugs and, therefore, these medications may be covered under Part D. However, antitussives used to treat cough symptoms, and not the underlying medical condition causing the cough, are excluded from basic Part D coverage regardless of the medical condition causing the cough.*
• Benzodiazepines
• Barbiturates

Part B vs Part D Guidelines *see* Medicare Prescription Drug Benefit Manual Chapter 6, Appendix C- Part B vs. D Coverage Issues

Durable Medical Equipment (DME) Supply Drugs These are drugs that require administration by the use of a piece of covered DME (e.g., a nebulizer, external or implantable pump) - they are covered as a supply necessary for the DME to perform its function. The largest Medicare expenditures for drugs furnished as a DME supply are for inhalation drugs, which are administered **in the home** through the use of a nebulizer (e.g., albuterol sulfate, ipratropium bromide). These drugs are not covered under Part D for use with a nebulizer. However, if these drugs were delivered with a metered dose inhaler or other non-nebulized administration they would be Part D drugs. For the list of nebulizer drugs covered under Part B, refer to the Noridian DME MAC LCD for Nebulizers (L33370)

In the case of a beneficiary in a hospital, or a SNF bed, (1) who does not have Part A coverage, (2) whose Part A coverage for the stay has run out or (3) whose stay is non-covered—inhalation DME supply drugs are not covered under Part B because the law limits coverage under Part B's DME benefit to those items that are furnished for use in a patient's home, and specifies that a ***hospital or SNF cannot be considered the beneficiary's "home" for this purpose***. In this case, coverage for the drugs would be available under Part D.

In addition to a hospital, a SNF or a distinct part SNF, the following facilities **cannot be considered a home** for purposes of receiving the Medicare DME benefit:

- a nursing home that is dually-certified as both a Medicare SNF and a Medicaid nursing facility (NF);
- a Medicaid-only NF that primarily furnishes skilled care;
- a non-participating nursing home (i.e., neither Medicare or Medicaid) that provides primarily skilled care; and
- an institution which has a distinct part SNF and which also primarily furnishes skilled care.

Infusion Pump Medications
Infusion pumps are medical devices used to deliver solutions containing parenteral drugs under pressure at a regulated flow rate. There is a National Coverage Determination (NCD) 280.14 on infusion pumps. Click here to review. The NCD specifies indications and limitations of coverage.

In general, the supplier would bill Part B if the drug was administered using an infusion pump and bill the Part D plan for infusion using other methods (e.g., IV push, IV minibag with pole). There is no Part B coverage in the home for infusion drugs administered **without** an infusion pump (e.g., IV push, IV minibag with pole). While professional services and supplies related to the administration of the infused drug are not payable under Part D, some coverage may be available under Part A or B home health benefits, under Medicaid, or from secondary commercial health benefits.

As a rule, drugs infused using an implantable pump would be covered under Part B. CDPHP will consider implantable infusion pumps and associated services medically reasonable and necessary for the conditions listed in the NCD above. Any drug(s) used to fill the implantable pump must be appropriate for the treatment of the individual patient. Drugs compounded for the special needs of a patient may be covered. Drugs filling the pump are often obtained singly or mixed with other drugs from compounding pharmacies. Unless the medications are administered in the exact concentrations available from national pharmaceutical companies, the medications will be considered as compounded. Compounded medications created by a pharmacist in accordance with the Federal Food, Drug and Cosmetic Act may be covered under Medicare. A compounded drug is defined as a combination of drugs mixed by a pharmacist. This definition does not include a simple reconstitution of a drug as directed by the package insert. Drugs currently approved for pain management through an implantable infusion pump include: bupivacaine, clonidine, droperidol, fentanyl, hydromorphone, ketamine, morphine, Prialt, sufentanil, and tetracaine.

Drugs infused in the home using an external pump are covered under Part B if they are included under the local coverage policy of the applicable Medicare DME MAC. *If the drug is being administered in the home with an infusion pump but the drug is **not covered** by the DME MAC policy then coverage should be considered under **Part D** based on whether the drug is on formulary.*

In the case of a beneficiary in a hospital or a SNF bed: (1) who does not have Part A coverage, (2) whose Part A coverage for the stay has run out, or (3) whose stay is non-covered—infusible DME supply drugs are not covered under Part B because the law limits coverage under Part B's DME benefit to those items that are furnished for use in a patient's home, and specifies that a hospital or SNF cannot be considered the beneficiary's "home" for this purpose. In this case, coverage for the drugs would be available under Part D.

In addition to a hospital, a SNF or a distinct part SNF, the following facilities **cannot be considered a home** for purposes of receiving the Medicare DME benefit:

- a nursing home that is dually-certified as both a Medicare SNF and a Medicaid nursing facility (NF);
- a Medicaid-only NF that primarily furnishes skilled care;
- a non-participating nursing home (i.e., neither Medicare or Medicaid) that provides primarily skilled care; and
- an institution which has a distinct part SNF and which also primarily furnishes skilled care.

Immunosuppressive Drugs Immunosuppressive therapy (such as cyclosporine) for a beneficiary who has received a **Medicare covered organ transplant** is covered under Part B; otherwise, the Part D plan is billed. Immunosuppressive drugs are substances that suppress or interfere with normal immune responses. They are used in controlling autoimmune diseases and in enhancing the chances for survival of foreign-tissue grafts and transplants. Examples of immunosuppressive drugs include:

- azathioprine
- cyclosporine
- gengraf
- mycophenolate
- neoral
- Nulojix Inj
- Prograf

- prednisone/prednisolone/methylprednisolone (when used in conjunction with immunosuppressive drugs as part of a therapeutic regimen)
- Rapamune Soln
- Sandimmune
- sirolimus
- tacrolimus
- Zortress

Part D sponsors are responsible to determine Part B vs. Part D coverage. Beginning in 2019, CMS will be launching a new web portal that will provide additional transplant information to plans. The portal is called Additional Beneficiary Information Initiatives (ABII) and will be part of a group of Acumen web portals. CMS will begin populating ABII with Medicare covered non-kidney transplant data derived from Medicare fee-for-service claims.

On April 1, 2019, the Centers for Medicare and Medicaid (CMS) issued a memo titled, "Using CMS Data when making B vs D Coverage Determinations for Immunosuppressants used to Prevent Transplant Rejections." In this memo, CMS clarifies that the kidney transplant data transmitted to plans via the Transaction Reply Report (TRR) has not been aligned with the member's Medicare Part A or Part B entitlement period. Members with End Stage Renal Disease (ESRD) and/or kidney transplants can have multiple, non-contiguous Medicare entitlement periods. Non-kidney transplant data provided via the Additional Beneficiary Information Initiative (ABII) database has already been checked against Medicare entitlement, so there is no issue using this data to make a Part B vs Part D determination.

Because kidney transplant data in the TRR may not reflect whether Medicare paid for the transplant, Part D sponsors may receive a TRR specifying a renal transplant date which does not fall within the Medicare entitlement periods presented within MARx. This has led to plan confusion as to whether the renal transplant was covered by Medicare or not. CMS clarified that it is critical that Part D sponsors always utilize ***both*** the transplant date and Medicare entitlement data provided via MARx when making these B vs D determinations. The Medicare entitlement data transmitted to plans via the TRR is only for the most recent entitlement period and may not reflect prior entitlements. Therefore, the plan must manually check MARx for previous Medicare entitlement periods.

CDPHP will utilize an Excel file which is updated to reflect members being passed on the TRR with transplant codes (i.e., 269) and ABII files. This file contains all member info including the Medicare eligibility dates from MARX. If the member was eligible for Medicare at the time they had their transplant, then the transplant was covered by Medicare and the drugs will process under Part B.

1. No Prior Part D Claims History for Immunosuppressants

a) The plan has received information from CMS (e.g., via MARx or ABII) indicating that Medicare covered the enrollee's transplant or, in the case of a Medicare Advantage enrollee, the MA Plan has medical claims history of a covered transplant regardless of previously received information from a prescriber on whether or not the transplant was covered by Medicare.

In this situation, plans are expected to rely on the CMS information (or in the case of an MA plan, its own medical claims history) and cannot cover Immunosuppressants under Part D even if information is also provided by the prescriber that indicates that the transplant was not Medicare covered.

b) The plan has **not** received information from CMS (via MARx or ABII) indicating that Medicare covered the transplant for the enrollee; in the case of a Medicare Advantage enrollee, the MA Plan does not have medical claims showing a history of a covered transplant; and the plan has not previously received information from a prescriber that the transplant was covered by Medicare.

In this situation, CMS expects plans to default to covering the Immunosuppressants under Part D and no longer expects plans to reach out to prescribers to inquire about Medicare coverage of the transplant. Such outreach is burdensome for plans and prescribers, and has been shown to be unreliable for accurately determining if Medicare covered a transplant. Nevertheless, the plan should approach this coverage decision using the best available information; if the plan has previously reached out to the prescriber and received information indicating that the that the transplant was covered by Medicare (in full or in part), the Part D plan may not cover Immunosuppressants under D.

2. Prior Part D Claims History <u>and</u> either MARx nor ABII currently indicates that Medicare covered the transplant:

A plan might have covered the drugs under Part D previously because either:

- MARx information was updated after the Part D sponsor relied on prior information from the prescriber that the transplant was NOT covered/ paid by Medicare; or

- The Part D sponsor had relied solely on information from the prescriber that the transplant was NOT covered/paid by Medicare without regard to MARx.

Under either scenario, the Part D sponsor must now rely on the MARx information **going forward** and notify the enrollee that the plan can no longer cover the immunosuppressant(s) under Part D because it is covered under Medicare Part B. No changes need to be made to prior Part D claims.

3. Prior Part D Claims History, no MARx indicator or MA plan medical claims history of a covered transplant BUT the Part D sponsor receives information from CMS that the transplant was covered by Medicare (e.g., Part D sponsor receives the information from CMS as part of a CMS Program Integrity audit or through ABII).

Under this scenario, the Part D sponsor must now rely on the CMS information **going forward** and provide notice to the enrollee that the plan will no longer cover the immunosuppressant(s) under Part D because it is covered under Medicare Part B. No changes need to be made to prior Part D claims.

Hemophilia Clotting Factors Hemophilia clotting factors are covered under Part B for patients competent to use such factors to control bleeding without medical supervision of factors and items related to the administration of such factors. These would not be covered under Part D.

Oral Anti-Cancer Drugs and Oral Anti-Emetics

Oral Chemotherapy (with potential for non-cancer indications)
If the medication is taken orally during chemotherapy and there is an infusible form of the drug that would be covered incident to a physician's visit the medication is covered under Part B; otherwise, it is covered under Part D (i.e., CYTOXAN or cyclophosphamide)

Oral Chemotherapy (with cancer indications only)
The following medications are **always** covered under the **Part B benefit** since they are always indicated for treatment of cancer (no non-cancer indications).

- capecitabine (XELODA)
- temazolamide (TEMODAR)

Oral Anti-Emetics If the oral anti-emetic is being used in relation to cancer treatment **and** as a full replacement for intravenous administration within 48 hours of cancer treatment, then they would be covered under Part B. If such drugs are dispensed for use **after** the 48-hour period **or** are prescribed for conditions other than the effects of cancer treatment, then they would be covered under Part D. The following are a list of examples (may not be all inclusive):

- dronabinol caps
- granisetron tabs
- ondansetron

The following drugs will follow the criteria set forth in the DME MAC Local Coverage Determination for Anti-Emetics. In addition to the LCD the related coverage article A52480 will detail the specific antiemetic drugs listed below**.**

- AKYNZEO caps (netupitant-palonosteron)
- EMEND (aprepitant)
- VARUBI tabs (rolapitant)

Criteria for Approval - AKYNZEO

1. The drug is being used as part of a cancer chemotherapy regimen
2. The oral anti-emetic formulation is being used as a full therapeutic replacement for an IV anti-emetic drug that would otherwise have been administered at the time of chemotherapy. *This criterion is not met when the chemotherapy drug is an oral drug or when the chemotherapy drug is administered intravenously in the home setting because the type and dosage of chemotherapy drugs administered in these situations do not require intravenous antiemetic drugs*
3. The oral drug must be given within 48 hours of chemotherapy
4. Akynzeo must be given as part of a regimen that includes an oral corticosteroid (i.e., dexamethasone)

5. The member must be receiving one or more of the following chemotherapeutic agents: Alemtuzumab, Azacitidine, Bendamustine, Carboplatin, Carmustine, Cisplatin, Clofarabine, Cyclophosphamide, Cytarabine, Dacarbazine, Daunorubicin, Doxorubicin, Epirubicin, Idarubicin, Ifosfamide, Irinotecan, Lomustine, Mechlorethamine, Oxaliplatin, Streptozocin

Criteria for Approval - EMEND, aprepitant and VARUBI (rolapitant)

1. The drug is being used as part of a cancer chemotherapy regimen
2. The oral antiemetic formulation is being used as a full therapeutic replacement for an IV antiemetic drug that would otherwise have been administered at the time of chemotherapy. *This criterion is not met when the chemotherapy drug is an oral drug or when the chemotherapy drug is administered intravenously in the home setting because the type and dosage of chemotherapy drugs administered in these situations do not require intravenous antiemetic drugs*
3. The oral drug must be given within 48 hours of chemotherapy
4. Varubi (rolapitant)/ Emend (aprepitant) must be given as part of a regimen that includes an oral corticosteroid (i.e., dexamethasone) and an oral 5-HT3 antagonist (i.e., ondansetron, granisetron)
5. The member must be receiving one or more of the following chemotherapeutic agents: Alemtuzumab, Azacitidine, Bendamustine, Carboplatin, Carmustine, Cisplatin, Clofarabine, Cyclophosphamide, Cytarabine, Dacarbazine, Daunorubicin, Doxorubicin, Epirubicin, Idarubicin, Ifosfamide, Irinotecan, Lomustine, Mechlorethamine, Oxaliplatin, Streptozocin

Immunizations Influenza and pneumococcal vaccines are always covered under Part B**.** Hepatitis B vaccine coverage depends on the risk of the individual. If the individual is at high or intermediate risk then Part B would cover. If the individual was at low risk then Part D would cover. In addition, there are some vaccines that may be covered under Part B if they are being administered because they are directly related to the treatment of an injury or direct exposure to a disease (i.e., Tetanus/diphtheria or Rabies). As of 1/1/2022 COVID-19 vaccine will be covered under Part B. For a list of complete vaccine coverage please go to cdphp.com and search for Medicare Vaccine Coverage guide.

Antigens These are prepared by a physician (usually an allergist) for a specific patient. The physician or physician's nurse generally administers them in the physician's office. In some cases, the physician prepares antigens and furnishes them to a patient who has been taught to self-administer them at home. There is no Part D coverage for antigens; they are always covered under Part B.

Parenteral Nutrition or Intradialytic parenteral nutrition (IDPN) If the therapy is being provided because of a non-functioning digestive tract then Part B would cover, otherwise these are Part D drugs.

Erythropoietin (EPO) EPO is covered for the treatment of anemia for patients with chronic renal failure who are on dialysis. When EPO is given in conjunction with dialysis (i.e., at the facility) it is considered covered under the per diem rate that CDPHP pays to the facility and it should be supplied by the facility. The member should not be filling under their Part D coverage at the pharmacy.

EPO is also covered for hip or knee surgery candidates at high risk for preoperative transfusions with significant anticipated blood loss and who meet all of the following criteria per the Medicare Benefit Policy Manual, Chapter 15, 50.5.2.2

- Members with anemia and a hemoglobin between 10 and 13 mg/dL
- Members who are not candidates for autologous blood transfusions
- Members who are expected to lose more than 2 units of blood
- Members who have had a work-up which indicates that their anemia appears to be that of chronic disease

Erythropoiesis Stimulating Agents (ESAs) **are covered** in cancer and related neoplastic conditions **only** in accordance with Medicare criteria. See the NCD for Erythropoiesis Stimulating Agents (ESAs) in Cancer and Related Neoplastic Conditions (110.21).

Nationally Covered Indications
ESA treatment for the anemia secondary to myelosuppressive anticancer chemotherapy in solid tumors, multiple myeloma, lymphoma, and lymphocytic leukemia is only reasonable and necessary under the following specified conditions:

- The hemoglobin level immediately prior to initiation or maintenance of ESA treatment is < 10 g/dL (or the hematocrit is < 30%).
- The starting dose for ESA treatment is the recommended FDA label starting dose, no more than 150 U/kg/3 times weekly for epoetin and 2.25 mcg/kg/1 time weekly for darbepoetin alpha. Equivalent doses may be given over other approved time periods.
- Maintenance of ESA therapy is the starting dose if the hemoglobin level remains below 10g/dL (or hematocrit is < 30%) 4 weeks after initiation of therapy and the rise in hemoglobin is ≥ 1g/dL (hematocrit ≥ 3%);

- For patients whose hemoglobin rises < 1g/dl (hematocrit rise < 3%) compared to pretreatment baseline over 4 weeks of treatment and whose hemoglobin level remains < 10g/dL after the 4 weeks of treatment (or the hematocrit is < 30%), the recommended FDA label starting dose may be increased once by 25%. Continued use of the drug is not reasonable and necessary if the hemoglobin rises < 1g/dl (hematocrit rise < 3%) compared to pretreatment baseline by 8 weeks of treatment.
- Continued administration of the drug is not reasonable and necessary if there is a rapid rise in hemoglobin > 1g/dl (hematocrit > 3%) over 2 weeks of treatment unless the hemoglobin remains below or subsequently falls to < 10g/dL (or the hematocrit is < 30%). Continuation and reinstitution of ESA therapy must include a dose reduction of 25% from the previously administered dose.
- ESA treatment duration for each course of chemotherapy includes the 8 weeks following the final dose of myelosuppressive chemotherapy in a chemotherapy regimen.

Nationally Non-Covered Indications
ESA treatment is not reasonable and necessary for beneficiaries with certain clinical conditions, either because of a deleterious effect of the ESA on their underlying disease or because the underlying disease increases their risk of adverse effects related to ESA use. These conditions include:

- Any anemia in cancer or cancer treatment patients due to folate deficiency, B-12 deficiency, iron deficiency, hemolysis, bleeding, or bone marrow fibrosis;
- The anemia associated with the treatment of acute and chronic myelogenous leukemias (CML, AML), or erythroid cancers;
- The anemia of cancer not related to cancer treatment;
- Any anemia associated only with radiotherapy;
- Prophylactic use to prevent chemotherapy-induced anemia;
- Prophylactic use to reduce tumor hypoxia;
- Patients with erythropoietin-type resistance due to neutralizing antibodies; and
- Anemia due to cancer treatment if patients have uncontrolled hypertension.

Members may have additional coverage of EPO under their Part D Prescription Drug benefit that is not addressed in this policy. See Part D policy 1350/20.000278 for drugs on the Part D formulary that require PA.

ESRD Drugs
The following drugs will be stopped for a determination at the pharmacy when there is an indicator in the member's eligibility that states **DIALYSIS = YES**.

A. If it is confirmed that the member is on dialysis **and** the drug is being given at the dialysis facility during dialysis then the drug should be covered as part of the per diem rate that CDPHP pays to the facility.
B. If the member is on dialysis and the drug is taken daily or being used outside the dialysis facility then the claim should process under the Part B benefit.
C. If the member is not on dialysis then the claim should process under Part D if it has FDA indications outside of dialysis.

- calcitriol caps/injection
- cinacalcet tabs
- heparin sodium injection 1000u/ml, 5000u/ml, 10000u/ml, 20000u/ml
- ibandronate 150mg tabs
- levocarnitine 1gm/10ml oral soln, 333mg tab
- lidocaine inj 0.5%, 1%, 1.5%, 2%
- lidocaine/prilocaine cream
- pamidronate inj
- paricalcitol caps

Sensipar/Parsabiv: January 2018 change - see below

Drugs used for the provision of renal dialysis services are defined in 42 CFR 413.234(a) *as a drug or biological with no injectable equivalent or other form of administration other than an oral form.* Prior to January 1, 2018 Sensipar J0604 (cinacalcet) met the definition under 42 CFR 413.234(a) and was paid under the Part D benefit. A new injectable drug, Parsabiv® (J0606, etelcalcetide), that falls within the bone and mineral metabolism functional category was approved for renal dialysis services by the United States Food and Drug Administration (FDA) in 2017. Therefore, as of January 1, 2018 Sensipar will no longer be payable under the Part D benefit if the member is on dialysis. Since Parsabiv is only indicated for use in patients on hemodialysis and given as an injection at the end of the dialysis treatment it is considered part of the per diem rate that CDPHP pays the dialysis facility.

Oral Phosphate Binders: January 2025

Under 42 C.F.R. § 413.174(f)(6), effective January 1, 2025, payment to an ESRD facility for renal dialysis service drugs and biologicals with only an oral form furnished to ESRD patients is incorporated within the prospective payment system rates established by CMS in § 413.230 and separate payment will no longer be provided.

Effective January 1, 2025, the following oral-only phosphate binders are approved for the TDAPA under the ESRD PPS:

- sevelamer carbonate, sevelamer hydrochloride,
- sucroferric oxyhydroxide (Velphoro)
- lanthanum carbonate
- ferric citrate (Auryxia)
- calcium acetate

Vafseo (vadadustat)

The Transitional Drug Add-On Payment Adjustment (TDAPA) is a payment adjustment under the ESRD PPS for certain new renal dialysis drugs and biological products. In October 2024, CMS approved a TDAPA application for Akebia's VAFSEO® (vadadustat) under the ESRD PPS.

Xpozah (tenapanor)

On October 17, 2023, a new oral phosphate lowering agent received FDA marketing approval. According to the FDA label information for this drug, XPHOZAHTM (tenapanor) is indicated to reduce serum phosphorus in adults with chronic kidney disease who are on dialysis. CMS has identified XPHOZAHTM to be a renal dialysis service because it is used to treat or manage a condition associated with ESRD. Specifically, it is used as an add-on therapy in patients who have an inadequate response to phosphate binders or who are intolerant of any dose of phosphate binder therapy. CMS has also determined that XPHOZAHTM meets the current regulatory definition of an oral-only drug as defined at § 413.234(a), and therefore, in accordance with § 413.174(f)(6), is not paid for under the ESRD PPS until January 1, 2025. Consistent with policies adopted in the CY 2016 and CY 2023 ESRD PPS final rules (see 80 FR 69025 and 87 FR 67183), XPHOZAHTM will be included in the ESRD PPS effective January 1, 2025, using the drug designation process under § 413.234.

Intravenous and Subcutaneous Immune Globulin (IVIG and SCIg)

A. Intravenous Immune Globulin (IVIG) in the Home **See Medicare Benefit Policy Manual, Chapter 15, 50.6**

Intravenous immune globulin (IVIG) for the treatment of primary immune deficiency diseases is **covered** in the home under Part B if **all** of the following criteria are met:

- It is an approved pooled plasma derivative for the treatment of primary immune deficiency disease; and
- The patient has a diagnosis of primary immune deficiency disease (ICD-9 codes 279.04, 279.05, 279.06, 279.12, and 279.2 or ICD-10-CM codes D80.0, D80.5, D81.0, D81.1, D81.2, D81.6, D81.7, D81.89, D81.82, D81.9, D82.0, D83.0, D83.2, D83.8, or D83.9 if only an unspecified diagnosis is necessary); and
- The IVIG is administered in the home; and
- The treating physician has determined that administration of the IVIG in the patient's home is medically appropriate.

The supplier shall bill Part B is the diagnosis is Primary Immune Deficiency (see codes above). IVIG provided in the home for other diagnoses would be a Part D benefit and should be reviewed under Part D criteria policy 1350/20.000278.

B. Intravenous Immune Globulin (IVIG) in Office/Outpatient setting

Intravenous immune globulin (IVIG) will be covered as a Part B (medical) benefit if the product being given is for a medically accepted indication

C. Intravenous Immune Globulin (IVIG) for the Treatment of Autoimmune Mucocutaneous Blistering Diseases

IVIG **is covered** for the treatment of biopsy-proven: (1) Pemphigus Vulgaris, (2) Pemphigus Foliaceus, (3) Bullous Pemphigoid, (4) Mucous Membrane Pemphigoid (a.k.a., Cicatricial Pemphigoid), and (5) Epidermolysis Bullosa Acquisita.

For specific coverage guidelines refer to the National Coverage Determination (NCD) 250.3

D. Subcutaneous Immune Globulin (SCIg) Coverage **for the administration of SCIg using an external infusion pump is provided as stated in the** LCD External Infusion Pumps (L33794) **to be effective 7/18/2021. SQIg (codes below) is covered when criteria 1-3 AND criterion 4 OR 5 are met:**

1) The subcutaneous immune globulin preparation is a pooled plasma derivative which is FDA-approved; and
2) The SCIg is administered in the home; and,
3) The treating practitioner has determined that administration of the SCIg **in the patient's home** is necessary and appropriate; and,
4) The beneficiary has a primary immune deficiency disorder (Refer to the Group 3 ICD-10 code list in the LCD-related Policy Article for applicable diagnoses.); OR,
5) The beneficiary has a diagnosis of chronic inflammatory demyelinating polyneuropathy (CIDP) that has responded to IVIg treatment (Refer to the Group 6 ICD-10 code list in the LCD-related Policy Article for applicable diagnoses.).

SQIg Codes

CODE	DESCRIPTION
J1551	INJECTION, IMMUNE GLOBULIN (CUTAQUIG), 100MG
J1555	INJECTION, IMMUNE GLOBULIN (CUVITRU), 100 MG
J1558	INJECTION, IMMUNE GLOBULIN (XEMBIFY), 100 MG
J1559	INJECTION, IMMUNE GLOBULIN (HIZENTRA), 100 MG
J1561	INJECTION, IMMUNE GLOBULIN, (GAMUNEX-C/GAMMAKED), NON-LYOPHILIZED (E.G., LIQUID), 500 MG
J1562	INJECTION, IMMUNE GLOBULIN (VIVAGLOBIN), 100 MG
J1569	INJECTION, IMMUNE GLOBULIN, (GAMMAGARD LIQUID), NON-LYOPHILIZED, (E.G., LIQUID), 500 MG
J1575	INJECTION, IMMUNE GLOBULIN/HYALURONIDASE, (HYQVIA), 100 MG IMMUNEGLOBULIN
J7799	NOC DRUGS, OTHER THAN INHALATION DRUGS, ADMINISTERED THROUGH DME

Injectable Drugs for the Treatment of Osteoporosis Chapter 7 of the Medicare Benefit Policy Manual Section 50.4.3

Sections 1861(m) and 1861(kk) of the Act provide for coverage of FDA approved injectable drugs for the treatment of osteoporosis. These drugs are expected to be provided by a home health agency (HHA) to **female beneficiaries** who are currently receiving services under an open home health plan of care, who meet existing coverage criteria for the home health benefit and who meet the criteria listed below. These drugs are covered on a cost basis when provided by an HHA under the circumstances listed below.

The home health visit (i.e., the skilled nurse's visit) to administer the drug is covered under all fee-for-service Medicare (Part A or Part B) home health coverage rules. Coverage of the drug is limited to female beneficiaries who meet each of the following criteria:

- The individual is eligible for Medicare Part B coverage of home health services (the nursing visit to perform the injection may be the individual's qualifying service);
- The individual sustained a bone fracture that a physician certifies was related to post-menopausal osteoporosis; and
- The individual's physician certifies that she is unable to learn the skills needed to self-administer the drug or is otherwise physically or mentally incapable of administering the drug, and that her family or caregivers are unable or unwilling to administer the drug.

This drug is considered part of the home health benefit under Part B. Therefore, Part B deductible and coinsurance apply regardless of whether home health visits for the administration of the drug are covered under Part A or Part B.

Definitions

Not Usually Self- Administered (as defined by Medicare):

a. Administered: The term "administered" refers only to the physical process by which the drug enters the patient's body. It does not refer to whether the process is supervised by a medical professional (for example, to observe proper technique or side-effects of the drug). Injectable drugs, including intravenously administered drugs, are typically eligible for inclusion under the "incident to" benefit. With limited exceptions, other routes of administration including, but not limited to, oral drugs, suppositories, topical medications are considered to be usually self-administered by the patient.

b. Usually: For the purposes of applying this exclusion, the term "usually" means more than 50 percent of the time for all Medicare beneficiaries who use the drug. Therefore, if a drug is self-administered by more than 50 percent of Medicare beneficiaries, the drug is excluded from coverage and the contractor may not make any Medicare payment for it.

c. By the patient: The term "by the patient" means Medicare beneficiaries as a collective whole. Includes only the patients themselves and no other individuals (that is, spouses, friends, or other care-givers are not considered the patient).

GOVERNMENT PROGRAMS

MEDICARE ADVANTAGE: Subject to the terms and conditions noted in above application. Benefits for Medicare Part D prescription drugs are only available to enrollees who have elected a CDPHP Medicare Advantage Part D plan. The CDPHP Medicare Choices Part D plan products do not cover any prescription drugs not covered by Medicare, with the exception of additional coverage purchased with a group-enhanced rider. In addition, for those individuals enrolled in the CDPHP Medicare Advantage product who have not elected a Part D option, CDPHP only covers those prescription drugs covered by Medicare Parts A and B, not those covered by Part D. Coverage is available for any eligible Part D drug prescribed for a medically accepted indication as cited in one or more of the following references: American Hospital Formulary Service Drug Information, and DrugDex Information System. Coverage is available for any eligible Part D drug and biological used off label in an anti-cancer chemotherapeutic regimen for a medically accepted indication as cited in one or more of the following references: American Hospital Formulary Service Drug Information, DrugDex Information System, National Comprehensive Cancer Network (NCCN) Drugs and Biologics Compendium, Clinical Pharmacology and Wolters Kluwer Lexi-Drugs (Lexicomp). In addition, for Part D drugs utilized in anticancer chemotherapy regimens, coverage for additional off-label use may be available if scientific literature approved by the Secretary of Health and Human Services (Secretary) supports such use.

5/2022	Added codes for IVIG
10/2022	Updated all links
12/2022	Added new code for coverage of IVIG in the home effective 10/1/2022
8/2023	Updated all hyperlinks. Removed reference to Local Coverage Article for IVIG given in office setting A53446 as it is retired.
8/2024	Updated all hyperlinks
9/2025	Updated all hyperlinks

This Pharmacy Policy is the exclusive property of Capital District Physicians' Health Plan, Inc. (CDPHP®) and its affiliated companies, CDPHP Universal Benefits,® Inc. (CDPHP UBI), and Capital District Physicians' Healthcare Network, Inc. (CDPHN). The contents and form of this policy are proprietary to CDPHP. Any reproduction or replication of this policy without the express written permission of CDPHP, CDPHP UBI, and CDPHN is strictly prohibited. This policy is subject to contractual limitations and/or parameters established in any Employer sponsored Summary Plan Description (SPD) and/or Benefit Design Document (BDD).

Disclaimer Notice

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgment when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

Background

Some medications that are administered as part of the Part B benefit may have limitations of coverage. When these medications are limited, they typically have additional requirements that need to be met in order to ensure medical necessity and appropriate use. An example of a requirement can be step therapy. Step therapy is when a member is required to try a preferred medication before a non-preferred medication is approved.

All Part B Step Therapy is reviewed by the CDPHP Pharmacy and Therapeutics Committee. The committee will base clinical decisions on the strength of scientific evidence and standards of practice, including assessment of peer reviewed medical literature, pharmacoeconomic studies, outcomes research data, and other information as is deemed appropriate.

Step therapy requirements will apply to new starts of non-preferred medications and as part of the Part B benefit only.

Preferred medications include:

Class	Non-preferred	Preferred
Osteoporosis	Prolia (denosumab) Bosaya (denosumab-kyqq) Conexxence (denosumab-bnht) Jubbonti (denosumab-bbdz) Osvyrti (denosumab-desu) Ospomyv (denosumab-dssb) Stoboclo (denosumab-bmwo)	Bildyos (denosumab-nxxp) Enoby (denosumab-qbde)
Rituxan Biosimilars	Rituxan (rituximab) Rituxan Hycela (rituximab and hyaluronidase) Riabni (rituximab-arrx)	Ruxience (rituximab-pvvr) Truxima (rituximab-abbs)
Herceptin Biosimilars	Herceptin (trastuzumab) Herceptin Hylecta (trastuzumab and hyaluronidase) Ogivri (trastuzumab-dkst) Herzuma (trastuzumab-pkrb) Ontruzant (trastuzumab-dttb) Hercessi (trastuzumab-strf)	Trazimera (trastuzumab-qyyp) Kanjinti (trastuzumab-anns)
Avastin Biosimilars	Avastin (bevacizumab) Vegzelma (bevacizumab-adcd) Alymsys (bevacizumab-maly) Jobevne (bevacizumab-nwgd)	Mvasi (bevacizumab-awwb) Zirabev (bevacizumab-bvzr)
Multiple Sclerosis	Lemtrada (alemtuzumab)	Tysabri (natalizumab)
Blood Disorders/Biosimilars	Fylnetra (pegfilgrastim-pbbk) Stimufend (pegfilgrastim-fpgk) Udenyca (pegfilgrastim-cbqv) Ziextenzo (pegfilgrastim-bmez) Rolvedon (eflapegrastim-xnst) Ryzneuta (efbemalenograstim alfa-vuxw)	Neulasta (pegfilgrastim) Nyvepria (pegfilgrastim-apgf) Fulphila (pegfilgrastim-jmdb)
	Granix (tbo-filgrastim) Neupogen (filgrastim) Releuko (filgrastim-ayow)	Zarxio (filgrastim-sndz) Nivestym (filgrastim-aafi)

	Nypozi (filgrastim-txid)	
Eosinophilic Asthma	Cinqair (reslizumab)	Nucala (mepolizumab) Fasenra (benralizumab)
Osteoarthritis – Hyaluronic Acid	Durolane Euflexxa Gelsyn-3 Genvisc 850 Hymovis Supartz FX Synvisc-One Triluron Trivisc Hyalgan Visco-3 SynoJoint	Gel-One Monovisc Orthovisc

Summary	
Effective Date of Policy:	8/1/2026

Required Criteria for Approval	
All of the following conditions for the requested indication must be met in order to approve therapy	
Drug Class	**Clinical Criteria**
Osteoporosis	Preferred: **Bildyos (Q5162), Enoby (Q5167)** *Bildyos and Enoby for use in an FDA-approved indication does not require prior authorization.* Non-preferred: Prolia (J0897), Conexxence (Q5158), Jubbonti (Q5136), Ospomyv (Q5159), Stoboclo (Q5157), Bosaya (Q5161), Osvyrti (Q5166) *Non-preferred agents (Prolia or any biosimilar) use for any indication will require prior authorization.* Criteria for non-preferred agent: Prolia, Jubbonti, Stoboclo, Conexxence, Ospomyv, Osvyrti, or Bosaya may be used in the following scenarios: • For existing utilizers: This is a continuation of therapy • For New Starts: Requests for non-preferred denosumab products will require a previous trial and failure (defined as a decrease in BMD or a fracture while on osteoporosis therapy) of **BOTH** Bildyos and Enoby unless there is medical reason why Bildyos and Enoby cannot be used due to formulation differences in the inactive ingredient(s) (e.g., differences in stabilizing agent, buffering agent, and/or surfactant) which, according to the prescriber, would result in a significant allergy or serious adverse reaction (documentation required) Prolia and all biosimilars will be covered for FDA and compendia approved uses according to the LCD33394 and local coverage article A52399
Rituxan Biosimilars	Preferred: **Ruxience (Q5119), Truxima (Q5115)** *Preferred biosimilar products of Rituxan for use in an FDA-approved indication do not require prior authorization.* Non-preferred: Rituxan (J9312), Rituxan Hycela (J9311), Riabni (Q5123) *Non-preferred agents use for any indication will require prior authorization* Criteria for non-preferred agent (Rituxan, Rituxan Hycela, Riabni): Rituxan or Rituxan Hycela may be used in the following scenarios: • Member has failed treatment with **two** preferred rituximab biosimilar agents due to documented intolerable/significant adverse reactions **OR** • This is a continuation of therapy for Rituxan, Rituxan Hycela or non-preferred biosimilar Clinical criteria for use of a preferred rituximab biosimilar: • Medication is being requested for an FDA-approved indication or consensus guideline recommendation (i.e., NCCN guideline recommendation)

Herceptin Biosimilars	Preferred: **Trazimera (Q5116), Kanjinti (Q5117)** *Preferred biosimilar products of Herceptin for use in an FDA-approved indication do not require prior authorization.* Non-preferred: Herceptin (J9355), Herceptin Hylecta (J9356), Ogivri (Q5114), Herzuma (Q5113), Ontruzant (Q5112), Hercessi (Q5146) *Non-preferred agents use for any indication will require prior authorization* Criteria for non-preferred agent (Herceptin, Herceptin Hylecta, Ogivri, Herzuma, Ontruzant): Herceptin or Herceptin Hylecta may be used in the following scenarios: • Member has failed treatment with **two** preferred Herceptin biosimilar agents due to documented intolerable/significant adverse reactions **OR** • This is a continuation of therapy for Herceptin, Herceptin Hylecta or non-preferred biosimilar Clinical criteria for use of a preferred Herceptin biosimilar: • Medication is being requested for an FDA-approved indication or consensus guideline recommendation (i.e., NCCN guideline recommendation)
Avastin Biosimilars	Preferred: **Mvasi (Q5107), Zirabev (Q5118)** *Preferred biosimilar products of Avastin for use in an FDA-approved indication do not require prior authorization.* Non-preferred: Avastin (J9035), Alymsys (Q5126), Vegzelma (Q5129), Jobevne (Q5160) *Non-preferred agents use for any indication will require prior authorization EXCEPT:* **Ophthalmic use of Avastin does not require the use of a biosimilar.** Criteria for non-preferred agents (Avastin, Alymsys, Vegzelma, Jobevne): Avastin may be used in the following scenarios: • Member has failed treatment with **two** preferred Avastin biosimilar agents due to documented intolerable/significant adverse reactions **OR** • This is a continuation of therapy for Avastin or non-preferred biosimilar Clinical criteria for use of a preferred Avastin biosimilar: • Medication is being requested for an FDA-approved indication or consensus guideline recommendation (i.e., NCCN guideline recommendation) as noted in the local coverage article A52370
Multiple Sclerosis	Preferred: **Tysabri (J2323)** *Tysabri for use in an FDA-approved indication does not require prior authorization.* Non-preferred: Lemtrada (J0202) *Lemtrada for any use will require prior authorization.* Criteria for non-preferred agent (Lemtrada): • History of use of Tysabri with minimal clinical response to therapy **OR** • Member demonstrates intolerance to Tysabri **OR** • Member has contraindication to Tysabri **OR** • This is a continuation of therapy of Lemtrada Clinical criteria for non-preferred agent (Lemtrada): Lemtrada may be used in the following scenarios: • Diagnosis of a relapsing form of Multiple Sclerosis **AND** • Inadequate response to two or more drugs indicated for the treatment of Multiple Sclerosis

Blood Disorders/ Biosimilars – short acting	Preferred: **Zarxio Q5101, Nivestym Q5110** *Preferred agent use for an FDA-approved indication does not require prior authorization* Non-preferred: Neupogen J1442, Granix J1447, Releuko Q5125, Nypozi J3590 *Non-preferred agent use for any indication will require prior authorization.* Criteria for non-preferred agent: • Member has failed treatment with **two** preferred products due to documented intolerable/significant adverse reactions
Blood Disorders/ Biosimilars – longer acting	Preferred: **Neulasta J2506, Fulphila Q5108, Nyvepria Q5122** *Preferred agent use for an FDA-approved indication does not require prior authorization* Non-preferred: Udenyca Q5111, Ziextenzo Q5120, Stimufend Q5127, Fylnetra Q5130, Rolvedon J1449, Ryzneuta J9361 *Non-preferred agent use for any indication will require prior authorization.* Criteria for non-preferred agent: • Member has failed treatment with **two** preferred products due to documented intolerable/significant adverse reactions
Eosinophilic Asthma	Preferred: **Nucala (J2182), Fasenra (J0517)** *Preferred agent use for an FDA-approved indication does not require prior authorization* Non-preferred: Cinqair (J2786) *Non-preferred agent use for any indication will require prior authorization.* Criteria for non-preferred agent: • Member has failed treatment with **both** Nucala and Fasenra due to documented intolerable/significant adverse reactions OR • This is a continuation of therapy for Cinqair
Osteoarthritis	Preferred: **Gel-One (J7326), Monovisc (J7327) and Orthovisc (J7324)** *Preferred agent use for an FDA-approved indication does not require prior* Non-preferred: Durolane: (J7318); Genvisc 850: (J7320); Supartz FX: (J7321); Hymovis: (J7322); Euflexxa: (J7323); Synvisc-One: (J7325); Gelsyn-3: (J7328); Trivisc: (J7329); Triluron: (J7332), Hyalgan (J7321), Visco-3 (J7321), SynoJoint (J7331) *Non-preferred agent use for any indication will require prior authorization.* Criteria for non-preferred agent: • Member has failed treatment with **two** preferred hyaluronic acid products due to documented intolerable/significant adverse reactions

Continuation Criteria

- Requests will be reviewed per criteria every 12 months.

Considerations

- This policy does not apply to medications being obtained through the Part D pharmacy benefit
- Prior authorization is obtained through the CDPHP pharmacy department.
- Step therapy Criteria **only applies to new-starts** of non-preferred medications.

GOVERNMENT PROGRAMS

MEDICARE ADVANTAGE:

Subject to the terms and conditions noted in above application. Benefits for Medicare Part D prescription drugs are only available to enrollees who have elected a CDPHP Medicare Advantage Part D plan. The CDPHP Medicare Advantage Part D plan products do not cover any prescription drugs not covered by Medicare, with the exception of additional coverage purchased with a group-enhanced rider. In addition, for those individuals enrolled in the CDPHP Medicare Advantage product who have not elected a Part D option, CDPHP only covers those prescription drugs covered by Medicare Parts A and B, not those covered by Part D. Coverage is available for any eligible Part D drug prescribed for a medically accepted indication as cited in one or more of the following references: American Hospital Formulary Service Drug Information, and DrugDex Information System. Coverage is available for any eligible Part D drug and biological used off-label in an anti-cancer chemotherapeutic regimen for a medically accepted indication as cited in one or more of the following references: American Hospital Formulary Service Drug Information, DrugDex Information System, National Comprehensive Cancer Network (NCCN) Drugs and Biologics Compendium, Clinical Pharmacology and Wolters Kluwer Lexi-Drugs (Lexicomp). In addition, for Part D drugs utilized in anti- cancer chemotherapy regimens, coverage for additional off-label use may be available if scientific literature approved by the Secretary of Health and Human Services (Secretary) supports such use.

CDPHP Pharmacy Services 8/1/2026

New: 1/2022

Effective Date	Changes Made
1/1/2022	New
8/2022	Reviewed, no changes needed
10/2022	Added Alymsys
3/2023	Added Vegzelma, updated link for A52370, removed hyperlink for A52452, retired
5/2023	Added statement that P and T Committee reviews all Part B Step Therapy
8/2023,8/2024	Reviewed, no changes needed
12/2024	Riabni moved from Preferred to Non-preferred Ogivri, Herzuma, Ontruzant moved from Preferred to Non-preferred Vegzelma and Alymsys moved from Preferred to Non-preferred Blood Disorders/Biosimilars Long and Short Acting added as new category Eosinophilic Asthma added as a new category Osteoarthritis-Hyaluronic Acid added as a new Category
9/2025	Added all denosumab biosimilars for Prolia as non-preferred agents Removed all additional plan criteria for Prolia and biosimilars and added links to LCD and local coverage article for guidance beyond step therapy
8/2026	Updated denosumab biosimilars and preferred agents

MEDICAL POLICY

Medical Policy Title	**Abdominoplasty, Panniculectomy, and Lipedema Reduction Surgery**
Policy Number	**7.01.53**
Current Effective Date	**November 1, 2026**
Next Review Date	**May 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

Abdominoplasty

I. An abdominoplasty (tummy tuck) including umbilical transposition and fascial plication for repair diastasis recti, or belt lipectomy (lower body lift) is considered cosmetic and, therefore, is **not medically necessary** for all indications.

Panniculectomy

II. A panniculectomy is considered **medically appropriate** when **ALL** of the following criteria are met:

   A. The panniculus is Grade 2 or higher (covering the genitals and upper thigh crease), documented by photographs;

   B. A clinically significant skin integrity-related functional impairment resulting from a documented recurrent or persistent medical condition directly related to excess tissue and skin folds of the pannus (e.g., intertrigo, dermatitis, cellulitis, panniculitis, ulceration, or necrosis) which is **both**:

      1. Documented by color photographs;

      2. Refractory to at least three (3) months of prescribed standard medical management with documented adherence to **both** of the following:

         a. Hygiene practices and applicable wound care; **and**

         b. Systemic antibiotics, antifungal agents, or corticosteroids;

   C. There is a documented expectation that surgery will improve or resolve the significant skin integrity-related functional impairment;

   D. If the member has had significant weight loss, medical records must document **either** of the following:

      1. For weight loss as a result of bariatric surgery, **all** of the following must be met:

a. A minimum of 18 months has elapsed from the date of the bariatric surgery;

b. Stable weight has been maintained for at least six (6) months prior to the consultation for panniculectomy; **and**

c. Post-operative weight loss is documented by **one (1)** of the following:

i. Body mass index (BMI) is less than or equal to 30 kg/m^2;

ii. Percentage of excess weight loss (%EWL) greater than or equal to 40%, calculated from the documented pre-intervention weight; **or**

iii. At least a 100-pound weight loss; **or**

2. For weight loss not related to bariatric surgery, **both** of the following must be met:

a. BMI is less than or equal to 30 kg/m^2; **and**

b. Stable weight has been maintained for at least six (6) months prior to the consultation for panniculectomy.

III. A panniculectomy is considered **not medically necessary** for all other indications, including but not limited to:

A. Improving appearance or self-esteem;

B. Correction for poorly fitting clothes or problems with hygiene;

C. Treatment of superficial inflammation or infection when controlled only with topical medications;

D. Treatment of neck or back pain;

E. When performed as an adjunct to other medically necessary abdominal or gynecological surgery (e.g., ventral hernia repair, bariatric surgery, hysterectomy, pelvic procedures), unless panniculectomy criteria are met separately.

<u>Lipedema Reduction Surgery</u>

IV. Lipectomy or liposuction for the treatment of lipedema is considered **medically appropriate** when **ALL** of the following criteria are met:

A. Documented diagnosis of lipedema established by clinical history and physical examination, supported by **all** of the following:

1. Palpable nodules in the adipose tissue;

2. Bilateral, symmetric excess adipose tissue deposition in the extremities;

3. Absence of pitting edema;

4. Easy bruising;

5. Pressure induced pain or tenderness to palpation at affected areas **and**

6. Negative Stemmer sign;

B. Lipedema results in **either** of the following:

1. A clinically significant physical functional deficit (e.g., difficulty ambulating or performing activities of daily living); **or**
2. A documented medical complication (e.g., recurrent cellulitis);

C. Signs and symptoms have not responded to at least six (6) consecutive months of optimal conservative medical management (e.g., weight loss, exercise compression garment/devices, and manual lymphatic drainage);

D. The post-operative treatment plan includes use of compression garments as instructed and continuation of conservative treatment, to maintain benefits, including weight management.

V. Lipectomy or liposuction is considered cosmetic and **not medically necessary** when performed solely for the removal of excess adipose tissue in the absence of a documented functional deficit. However, lipectomy may be an integral part of other covered services.

RELATED POLICIES

Corporate Medical Policy

Cosmetic & Reconstructive Surgery, 1370/20.000071

POLICY GUIDELINE(S)

I. Preoperative photographs are an absolute requirement for determination of medical appropriateness.

II. Documentation of functional impairment(s) (e.g., inability to perform activities of daily living), all prescribed standard medical management, and weight trends can be documented by any of the member's treating providers, including but not limited to the performing surgeon, primary care physician, and/or specialist (e.g., wound care, dermatology).

III. The criteria for panniculectomy apply regardless of the cause of the excess fatty tissue or redundant skin. These criteria apply to removal of fatty tissue or redundant (excessive) skin caused by obesity and apply to weight loss due to any reason, including bariatric surgery.

IV. A panniculectomy is ideally performed after the patient maintains a stable weight for two (2) to six (6) months. For post-bariatric surgery patients, this often occurs 12-18 months after surgery or at the 25 kg/m^2 to 30 kg/m^2 weight range (ASPS 2017).

V. The American Society of Plastic Surgeons' (2017) grading system for the severity of abdominal deformities is as follows:

Grade 1: Panniculus covers hairline and mons pubis but not the genitals

Grade 2: Panniculus covers genitals and upper thigh crease

Grade 3: Panniculus covers upper thigh

Grade 4: Panniculus covers mid-thigh

Grade 5: Panniculus covers knees and below

DESCRIPTION

The American Society of Plastic Surgeons (2017) defines the following:

Abdominoplasty ("tummy tuck") is a procedure typically performed for cosmetic purposes, involving the removal of excess skin and fat from the pubis to the umbilicus or above, and may include fascial plication of rectus muscle diastasis and neoumbilicoplasty.

Circumferential lipectomy (also known as belt lipectomy or lower body lift) combines the elements of an abdominoplasty or panniculectomy with removal of excess skin and fat from the lateral thighs and buttocks. The procedure removes a "belt" of tissue from around the circumference of the lower trunk, eliminating lower back rolls and providing elevation of the outer thighs, buttocks, and mons pubis. It may include suction-assisted lipectomy where necessary.

Panniculectomy involves the removal of a hanging pannus of excess skin and fat in a transverse or vertical wedge but does not include muscle plication, neoumbilicoplasty, or flap elevation. Unlike abdominoplasty, panniculectomy does not involve abdominal muscle tightening. Deformities associated with massive weight loss vary depending on body type, fat deposition pattern, and the amount of weight gained or lost. These deformities can lead to inability to exercise, impaired ambulation, chronic back, neck, and shoulder pain, difficulty with hygiene, and symptoms such as uncontrolled intertrigo, infections, and skin necrosis.

Lipedema

Lipedema is a chronic, progressive disorder characterized by abnormal distribution of subcutaneous adipose tissue, accompanied by pain or discomfort in affected areas. It predominantly affects women, often with a family history, and is frequently misdiagnosed as obesity or lymphedema. Lipedema typically presents with bilateral, disproportionate fat accumulation in the extremities (including the hips, buttocks, legs, and thighs), characteristically sparing the hands and feet. The arms may also be affected without edema of the hands. The presence of a nodular or fibrotic texture is palpable in affected areas.

Symptoms include heaviness, pain with pressure, easy bruising, loss of strength, and reduced daily activity levels that significantly affect health and quality of life. The excessive fat deposits are typically unresponsive to diet, exercise, or bariatric surgery. Lipedema typically presents with a negative Stemmer sign (ability to pinch the dorsal skin of the second toe), which helps distinguish it from lymphedema. However, a positive Stemmer sign does not rule out lipedema and likely indicates concomitant lymphedema (termed "lipo-lymphedema").

Untreated lipedema may result in secondary problems, including osteoarthritis and reduced mobility. Over time, the weight of excessive fat can impair the ability to walk. Initially, the lymphatic system can manage the increased interstitial fluid, but in later stages, secondary lymphedema (lipo-lymphedema) can occur if the fatty deposits compromise lymphatic function.

There is no cure for lipedema. The goal of therapy is to reduce symptoms, disability, and functional limitations and to prevent disease progression. Conservative treatment includes manual lymphatic

drainage, compression garments, intermittent pneumatic compression, skin care, and exercise. Individuals with lipedema may have obesity as a comorbidity, and dietary guidance is frequently prescribed. Conservative care may alleviate symptoms, but benefits are often short-lived and may require repeat treatment. For individuals who do not respond to conservative treatment, liposuction may be recommended.

SUPPORTIVE LITERATURE

Badran et al (2023) performed a dose-response meta-analysis of 22 studies (n=493) evaluating metabolic changes after surgical fat removal (SFR). Peak metabolic benefits at day 50 included reductions in body mass index (2 units), fat mass (3 kilograms), waist circumference (5 centimeters), serum leptin (15 µg/L), tumor necrosis factor-alpha (TNF-a; 0.75 pg/mL), total cholesterol (0.25 mmol/L), and blood pressure (3.5 mmHg systolic/diastolic), but most returned to baseline by day 180. Only insulin sensitivity showed sustained improvement beyond 6 months, with maximum reductions in fasting insulin (17 pmol/L) and Homeostatic Model Assessment for Insulin Resistance (HOMA-IR; 1 point) at day 180. No significant changes were observed in lean body mass, serum adiponectin, resistin, interleukin-6, C-reactive protein, triglycerides, low-density lipoproteins, free fatty acids, or fasting blood glucose. Key limitations include the small number of eligible studies with small sample sizes and heterogeneity introduced by pooling different SFR types (abdominoplasty vs. liposuction), which have dissimilar physiological effects on metabolic parameters. The authors recommended well-designed prospective studies to evaluate metabolic changes and safety beyond 6 months.

Liposuction for Lipedema

In 2021, a Delphi-based consensus on the standard of care for lipedema in the United States was created by a panel of 21 lipedema experts (Herbst 2021). According to the panel, lipedema reduction surgery is currently the only available technique for removing abnormal lipedema tissue (e.g., adipocytes, nodules, fibrotic extracellular matrix, and other non-adipocyte components). It is also the only treatment that slows progression of lipedema and ideally would be performed before complications and disabilities from lipedema develop. The panel found that lipedema reduction surgery significantly improves symptoms, mobility, stance, gait, valgus rotation/deformity of the knee and ankle, quality of life, and redistributes and restores the plantar arch. It also improves lymphatic symptoms, reducing the need for compression and manual therapy and improves lymphatic function as shown by radionucleotide lymphangioscintigraphy.

- Grade A consensus recommendations include that lipedema should be regarded as an LCT disease versus a disease of just adipocytes (fat); lipedema has a distinct distribution of pathologic tissue that differs from non-lipedema obesity.
- Grade B consensus recommendations include that lipedema LCT can affect the abdomen; lipedema tissue is resistant to reduction by diet, exercise, or bariatric surgery; rice-grain, pearl-sized or larger nodules in LCT should be part of the diagnostic criteria for lipedema; lipedema tissue is frequently painful especially when touched.
- Grade C consensus recommendations include that standard conservative therapy for lipedema

includes nutritional guidance, manual therapy, compression garments, pneumatic compression device (external pump), and home exercise.

Mortada et al (2024) performed a systematic review and meta-analysis of 20 prospective cohort studies (n=1,785 patients) assessing liposuction for lipedema. The majority of patients were stage 2 or 3, with tumescent liposuction being the most common technique (81%). Meta-analysis of nine studies revealed significant improvements in quality of life, pain, pressure sensitivity, bruising, cosmetic impairment, heaviness, walking difficulty, and itching (all $p<.0001$). Severe complications were rare, with no instances of shock, recurrence, or mortality. Mean follow-up was 15 months (range 1–96 months). Limitations included the absence of controlled trials, potential publication bias from prospective cohort designs, and limited generalizability, as 70% of studies originated from Germany. The authors concluded that liposuction, especially the tumescent technique, is effective in treating lipedema, enhancing outcomes across different modalities.

Fijany et al (2024) performed a meta-analysis of 10 studies encompassing 2,542 procedures on 906 patients, evaluating traditional tumescent liposuction (TTL), power-assisted liposuction (PAL), and water-assisted liposuction (WAL). All techniques showed significant improvements in pain, bruising, edema, tension, pressure sensitivity, and cosmetic and general impairment (all $p<0.00001$). Overall complication rates were low: TTL 1.5%, PAL 4.0%, WAL 0%, and combined PAL/WAL at 2.3%. Limitations included high heterogeneity for some outcomes and only one study using WAL exclusively, restricting definitive conclusions about technique superiority. The authors concluded that while all techniques are effective, further comparative studies are needed to establish optimal surgical approaches.

Kruppa et al (2026) published a Delphi consensus study in which experts from 19 countries reached consensus on 59 statements regarding the definition and management of lipedema. The panel defined lipedema as a chronic disease characterized by disproportionate, symmetrical expansion of subcutaneous adipose tissue in the extremities, accompanied by pain and sensitivity, with diagnosis relying on clinical history, physical examination, and exclusion of differential diagnoses, as no imaging or laboratory tests are officially approved for diagnostic verification. Conservative management (compression therapy, exercise, nutritional optimization, and Complex Decongestive Therapy) aims at symptom alleviation but does not achieve long-lasting benefits and cannot prevent disease progression. The panel reached consensus that lipedema reduction surgery is the only technique for removing pathological tissue and slowing progression, should be performed by providers with extensive lipedema knowledge as part of an integrated approach, and that lymph vessel-sparing surgery should be considered when there is potential for positive symptom impact. When lipedema coincides with obesity, treatment for obesity should be prioritized before surgery. The panel noted limited evidence overall, highlighting the need for further research and standardized reporting.

Vazirnia et al (2026) conducted a systematic review of 61 studies, composed of observational cohorts and case series with few randomized trials, evaluating lipedema diagnosis, clinical manifestations, and therapeutics, grading evidence using a modified Oxford scale. Conservative therapies including ketogenic diets, compression therapy, and aquatic exercise were associated with reduced pain and swelling (Grade 2A–2B evidence). Tumescent liposuction received a Grade 1 recommendation based on the strongest available evidence for sustained improvement in symptoms, mobility, and quality of

life. The authors noted that lipedema is a distinct, progressive condition requiring early recognition and intervention. Conservative therapies may provide partial relief, but tumescent liposuction remains the most effective treatment. Standardized diagnostic criteria, validated patient-reported outcomes, and clearer guidelines are needed to harmonize care and improve long-term outcomes.

PROFESSIONAL GUIDELINE(S)

Abdominoplasty

In 2018, the American Society of Plastic Surgeons (ASPS) reaffirmed the recommended insurance coverage criteria for third-party payers related to abdominoplasty. When abdominoplasty is performed solely to enhance appearance in the absence of any signs or symptoms of functional abnormalities, the procedure should be considered cosmetic in nature and not a compensable procedure.

Panniculectomy

In 2017, the ASPS issued a practice parameter for the surgical treatment of skin redundancy for obese and massive weight loss patients, outlining preoperative assessment and screening, management (e.g., timing, operative treatment), and postoperative care. A panniculectomy could be considered as a functional correction in patients who are of appropriate height and weight, and have a history of problems including panniculitis or chronic back pain that have persisted despite an adequate trial of non-surgical management, or have a functional impairment in activities of daily living/work, etc. Body contouring surgery is ideally performed after the patient maintains a stable weight for two (2) to six (6) months. For post-bariatric surgery patients, this often occurs 12 to 18 months after surgery or at the 25 kg/mg^2 to 30 kg/mg^2 weight range (ASPS 2017).

In 2019, the ASPS re-approved the recommended insurance coverage criteria for third-party payers related to panniculectomy. Panniculectomy should be considered a reconstructive procedure when performed to correct or relieve structural defects of the abdominal wall, improve skin health within the fold beneath the pannus, and/or help improve chronic low back pain due to functional incompetence of the anterior abdominal wall.

Liposuction for Lipedema

In 2022, the National Institute for Health and Care Excellence issued clinical guidance on liposuction for lipedema, recommending that liposuction for lipedema should be used only in the context of research because the evidence on safety and efficacy is inadequate.

Committee Approval Dates

New: 06/07

Revised: 05/08, 11/14, 07/15, 01/16, 03/18, 03/19, 7/21, 11/22, 3/23, 3/24, 3/25, 7/26 **Reviewed**: 05/09, 05/10, 05/11, 05/12, 05/13, 05/14, 05/16, 03/17, 3/20, 3/21, 3/22, 3/26	
Date	**Summary of Changes**
11/1/2026	• Transitioned Abdominoplasty, Panniculectomy & Abdominal Lipectomy policy 1370/20.000443 to Lifetime Healthcare Companies policy template and criteria.
4/1/2024 *No change to effective date of policy	• Clarified verbiage on type of panniculus that meets medical criteria. • Updated requirements for submitting medical photographs.
4/1/2024	• No criteria changes. • Updated policy name to Abdominoplasty, Panniculectomy and Abdominal Lipectomy. • Removed codes 15832, 15833, 15834, 15835, 15836, 15837, 15838, 15839, 15876, 15877, 15878, 15879 as these are addressed in the Cosmetic and Reconstructive Surgery policy.
4/1/2023	• Added clarification for lipectomy billed with a panniculectomy under Policy Considerations and abdominoplasty under Exclusions.
12/1/22 *No change to effective date of policy	• Added language to require original photographs
8/1/21	• Under the Position Statement, removed the separate criteria of the need to have a documented cellulitis and updated bullet 2 criteria to include cellulitis as a type of skin condition.

MEDICAL POLICY

Medical Policy Title	**Allergy Testing**
Policy Number	**2.01.10**
Current Effective Date	**January 1, 2026**
Next Review Date	**July 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. The following **allergy** tests are considered **medically appropriate** in the diagnosis of the allergic patient:

A. Percutaneous test(s) (scratch, puncture, prick) with allergenic extracts;

B. Combination of percutaneous (scratch, puncture, prick) and intracutaneous (intradermal) with venoms, drugs or biologics;

C. Intracutaneous (intradermal) test(s) with allergenic extracts, including airborne allergens;

D. Patch or application tests(s);

E. Photo patch test(s);

F. Photo test(s);

G. Inhalation bronchial challenge testing (not including necessary pulmonary function tests), with histamine, methacholine, or similar compounds;

* If dust, ragweed, or other common allergens are the suspected cause of the problem, this test is **not medically appropriate**, as skin tests can be used in these situations.

H. Ingestion challenge test;

I. Gammaglobulin (immunoglobulin), IgE;

J. Allergen-specific IgE **only** when testing for allergens (e.g., inhalant, food, insect, drug) under the following circumstances:

1. When direct skin testing is impossible due to extensive dermatitis or marked dermatographism;
2. For patients unable to discontinue use of interfering medications (e.g., antidepressants, antihistamines, or beta-blocking agents);
3. For patients who have had a near fatal reaction to an allergen;
4. In children younger than four (4) years of age;

5. In patients who will not or cannot cooperate with percutaneous testing due to mental or physical disease (e.g., Down syndrome, intellectual disability, dementia);
6. To follow patients with food allergies and/or insect sting allergies previously documented by history and in-vivo or in-vitro testing;
7. For patients with suspected latex allergy;
8. For patients with suspected insect sting allergy with prior negative skin testing; **or**
9. For patients with suspected penicillin allergy.

II. The following allergy tests are considered **investigational**:

A. Allergen-specific IgG (when above criteria are not met);
B. Leukocyte histamine release test (LHR);
C. Ophthalmic mucous membrane tests;
D. Direct nasal mucous membrane test;
E. Peanut allergen-specific quantitative assessment of multiple epitopes using enzyme-linked immunosorbent assay (ELISA);
F. Cytotoxicity, Provocative testing (e.g., Rinkel test), Rebuck skin window test.

III. Allergy and laboratory testing for a treatment program (e.g., Southern California Food Allergy Tolerance Induction Program) is considered **investigational**.

POLICY GUIDELINE(S)

Not Applicable

DESCRIPTION

Allergic or hypersensitivity disorders may be manifested by generalized systemic reactions and/or localized reactions in any organ system of the body. The reactions may be acute, subacute, or chronic, and immediate or delayed, and they may be caused by numerous offending agents (e.g., pollen, molds, dust, mites, animal dander, stinging insect venoms, foods, and drugs).

The optimum management of the allergic patient should include a careful history and physical examination and may include confirming the cause of allergic reaction by information from various testing methods. Once the offending allergenic agent(s) is (are) identified, treatment is provided by avoidance, medication, and/or immunotherapy.

Percutaneous Tests

The number of tests required may vary widely from patient to patient, depending upon the patient's history, and may require up to 80 tests. Allergy testing, any combination of percutaneous (scratch, puncture, prick) and intracutaneous is usually used when percutaneous testing is not considered to be sensitive enough to be the cause of an allergic reaction. The number of tests required may vary widely from patient to patient, depending upon the patient's history, and may require up to 40 tests.

Intracutaneous Tests

This may be used to represent serial endpoint testing (SET), which is a form of intradermal skin testing that uses increasing doses of antigen to determine the concentration at which the reaction changes from negative to positive (the "endpoint"). The test has been used for diagnosing allergic disorders and to guide the initiation of immunotherapy by using the endpoint dilution as the starting antigen dose. A physician or other qualified health care provider uses intracutaneous tests, sequential and incremental, with allergenic extracts for airborne allergens, immediate type reaction, to determine a patient's specific allergies. The number of tests must be specified (each sequential test = 1 unit). This includes test interpretation and provider report.

Patch or Application Tests

Also known as delayed hypersensitivity testing, this testing modality identifies allergens causing contact dermatitis. The suspected allergens are applied to the patient's back under dressings and allowed to remain in contact with the skin for 48 to 72 hours. The area is then examined for evidence of delayed hypersensitivity reactions.

Photo Patch Tests

This test reflects contact photosensitization. The suspected sensitizer is applied to a patch of skin for 48 hours. If no reaction occurs, the area is exposed to a dose of ultraviolet light sufficient to produce inflammatory redness of the skin. If the test is positive, a more severe reaction develops at the patch site than on the surrounding skin.

Inhalation Bronchial Challenge Test

Histamine or methacholine is used to perform this test, when it is necessary to determine whether the patient has hyper-responsive airways. Volatile chemicals are used to perform the test, when the allergy is encountered in an occupational setting.

Ingestion Challenge Test

With these tests, the patient ingests a food, drug or other substance to which sensitivity is suspected. This may be done in an open or blinded manner. Testing may be done at home, but in some instances of extreme suspected hypersensitivity, it may be performed in the office setting.

IgE Test

Total serum IgE concentration testing is not indicated in most allergic patients but may be indicated for patients suspected of having allergic bronchopulmonary aspergillosis, immune deficiency disease characterized by increased IgE levels (e.g., Wiskott-Aldrich syndrome, hyper-IgE staphylococcal abscess syndrome), IgE myeloma, pemphigoid, or a poorly controlled moderate-to-severe asthmatic patient being considered for possible anti- IgE treatment.

Leukocyte Histamine Release Test

The leukocyte histamine release test is a measurement of the amount of histamine released in-vitro. Varying concentrations of an allergen extract are added to the patient's peripheral blood leukocytes. Histamine is normally released as a consequence of the interaction of allergen with cell-bound IgE antibodies. If an individual is atopic to a specific antigen, the leukocytes will not release the histamine in-vitro. Only a limited number of allergens can be tested from a single aliquot of blood and quality control studies have shown considerable variability in the measurement of histamine results.

SUPPORTIVE LITERATURE

Ferastraoaru et al (2017) reported, in an independent analysis of 75 patients with over 1600 tests between January 2014 and May 2015, for comparison of skin-prick (SPT), intradermal (IDST), and serum-specific immunoglobulin E (ssIgE) testing, that IDST detected more additional environmental sensitizations, compared with ssIgE testing. The authors concluded that IDST may be useful when the SPT and/or ssIgE testing results are negative, but the exposure history indicates relevant allergic sensitization. Serology added only a little more information when both SPT and IDST results were negative, but may be useful in combination with SPT, if IDST cannot be performed.

Leukocyte histamine release testing (LHRT) is a technique to evaluate the in vitro release of histamine from leukocytes in response to an allergen. It provides an in vitro correlate to an in vivo allergic response. Published literature reflects that commercially available LHRT studies suffer from not having been performed in a blinded manner or do not indicate whether or not there were blinded interpretations of the tests. Some studies included patients with known allergies, which did not represent the same population with equivocal allergy histories that would undergo testing. Studies of LHRT are potentially prone to spectrum, referral, and ascertainment bias, and are not sufficient to permit conclusions on the diagnostic accuracy of the tests. It has been suggested that LHRT may be a valuable test in those patients with discordant results of skin prick testing and RAST testing, but studies focusing on this subgroup of patients have not been identified.

Poto et al (2023) stated that mast cells are multi-functional immune cells with complex roles in tissue homeostasis and disease. Cardiac mast cells (HCMCs) are strategically located within the human myocardium and express the high-affinity receptor (FcεRI) for IgE and can be activated by anti-IgE and anti-FcεRI. Autoantibodies to IgE and/or FcεRI have been found in the serum of patients with a variety of immune disorders. The authors compared the effects of different preparations of IgG anti-IgE obtained from patients with atopic dermatitis (AD) with rabbit IgG anti-IgE on the release of preformed (histamine and tryptase) and lipid mediators [prostaglandin D2 (PGD2) and cysteinyl leukotriene C4 (LTC4)] from HCMCs. Functional human IgG anti-IgE from one out of six AD donors

and rabbit IgG anti-IgE induced the release of pre-formed (histamine, tryptase) and de-novo synthesized mediators (PGD2 and LTC4) from HCMCs. Human IgG anti-IgE was more potent than rabbit IgG anti-IgE in inducing pro-inflammatory mediators from HCMCs. Human monoclonal IgE was a competitive antagonist of both human and rabbit IgG anti-IgE. The authors concluded that although functional anti-IgE autoantibodies rarely occur in patients with AD, when present, they could powerfully activate the release of pro-inflammatory and vasoactive mediators from HCMCs.

A number of procedures have been shown to be invalid for any clinical purpose. Studies of cytotoxic tests and provocation-neutralization tests have demonstrated that results are not reproducible. Electrodermal diagnosis and applied kinesiology have not been evaluated for efficacy. The "reaginic" pulse test and chemical analysis of body tissues have not been substantiated as valid allergy tests.

There is a lack of published research on the diagnostic accuracy of peanut allergen-specific quantitative assessment of multiple epitopes using ELISA (e.g., VeriMAP Peanut Diagnostic and VeriMAP Peanut Sensitivity, AllerGenis). The evidence is insufficient to determine the effects of the technology on health outcomes.

Suprun et al (2019) presents the quantification and validation of a Bead-Based Epitope Assay (BBEA) that through multiplexing of epitopes and multiple sample processing enables completion of large experiments in a short period of time, using minimal quantities of patients' blood. Peptides that are uniquely coupled to beads are incubated with serum or plasma samples, and after a secondary fluorophore-labeled antibody is added, the level of fluorescence is quantified with a Luminex reader. The signal is then normalized and converted to epitope-specific antibody binding values. The authors show that the effect of technical artifacts, i.e., well position or reading order, is minimal and batch effects can be easily estimated and eliminated from the data. The authors analyzed the relationship between IgE and IgG4 binding to 50 peanut epitopes in a cohort of 160 children. The authors state they showed that epitope-specific IgE alone was sufficient to distinguish between peanut allergic and non-allergic children; with IgG4 and IgG4-IgE ratio providing no additional information. Larger studies of epitope-specific antibody responses might be helpful in determining the role of IgG4 and different levels of peanut reactivity. To further advance the molecular allergy diagnostics and potentially bring it to the clinic, the authors have developed a Bead-Based Epitope Assay (BBEA) that allows high-throughput screening of samples and epitopes with significantly smaller volumes of serum or plasma compared to current molecular assays. BBEA provides greater sensitivity and reproducibility than microarrays and better resolution than component resolved diagnostics, making it a promising tool for the development of diagnostic and prognostic biomarkers. The authors concluded that epitope-specific antibody binding quantified with BBEA is highly reliable, reproducible and has greater sensitivity of epitope detection compared to peptide microarrays. IgE directed at allergenic epitopes is a sensitive biomarker of food allergy and can be used to predict allergy severity and phenotypes; and quantification of the relationship between epitope-specific IgE and IgG4 can further improve our understanding of the immune mechanisms behind allergic sensitization.

There is lack of published research showing the efficacy of Tolerance Induction Programs (e.g., Southern California Food Allergy Institute's Tolerance Induction Program) to treat food allergies. These treatment programs and the extensive testing required to participate in the treatment is considered investigational.

PROFESSIONAL GUIDELINE(S)

According to a March 2008 American Academy of Allergy, Asthma, and Immunology (AAAAI) practice parameter addressing Allergy Diagnostic Testing, IgE antibody assay technology has improved, with new high-binding capacity, solid-phase matrices, non-isotopic labels for detection antibodies, and standards calibrated to the World Health Organization IgE reference preparation. These enhancements have led to an evolution in assay methods from the first-generation qualitative assays (e.g., RAST, MAST, EAST), through the second generation semi-quantitative IgE assays (e.g., AutoCAP, Alastat, HYTech, Matrix, MagicLite), to the present state-of-the-art quantitative third generation autoanalyzers. Two third-generation immunoassays are the Immunocaptured System (Phadia) and the Immulite 2000 (Diagnostic Products Corp.), the chemistry of which is similar to the original RAST, but which employ non-isotopic labels and have more rapid throughput with improved precision, accuracy, and analytical sensitivity. Their automated chemistries report out allergen specific IgE antibody quantitatively. In a 2022 publication on Practice Parameters for Drug Allergy, a joint task force of the AAAAI, the American College of Allergy, Asthma and Immunology (ACAAI), and the Joint Council of Allergy, Asthma & Immunology included in its executive summary a statement validating the use of intracutaneous (intradermal) tests, which are generally used for specific allergens (e.g., Hymenoptera venoms and penicillin), but may also be applied if prick/puncture test results are negative, and there is a strong historical likelihood of clinical allergy to specific allergens.

REGULATORY STATUS

Clinical laboratories may develop and validate tests in-house and market them as a laboratory service. Laboratory-developed tests must meet the general regulatory standards of the Clinical Laboratory Improvement Amendments (CLIA).

Laboratories that offer laboratory-developed tests must be licensed by CLIA for high-complexity testing. More information is available at: Clinical Laboratory Improvement Amendments (CLIA) | FDA [accessed 2026 Jun 06].

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
95004	Percutaneous tests (scratch, puncture, prick) with allergenic extracts, immediate type reaction, including test interpretation and report, specify number of tests

Code	Description
95017	Allergy testing, any combination of percutaneous (scratch, puncture, prick) and intracutaneous (intradermal), sequential and incremental, with venoms, immediate type reaction, including test interpretation and report, specify number of tests
95018	Allergy testing, any combination of percutaneous (scratch, puncture, prick) and intracutaneous (intradermal), sequential and incremental, with drugs or biologicals, immediate type reaction, including test interpretation and report, specify number of tests
95024	Intracutaneous (intradermal) tests with allergenic extracts, immediate type reaction, including test interpretation and report, specify number of tests
95027	Intracutaneous (intradermal) tests, sequential and incremental, with allergenic extracts for airborne allergens, immediate type reaction, including test interpretation and report, specify number of tests
95028	Intracutaneous (intradermal) tests with allergenic extracts, delayed type reaction, including reading, specify number of tests
95044	Patch or application test(s) (specify number of tests)
95052	Photo patch test(s) (specify number of tests)
95056	Photo tests
95060 (E/I)	Ophthalmic mucous membrane tests
95065 (E/I)	Direct nasal mucous membrane test
95070	Inhalation bronchial challenge testing (not including necessary pulmonary function tests), with histamine, methacholine, or similar compounds
95076	Ingestion challenge test (sequential and incremental ingestion of test items, e.g., food, drug, or other substance); initial 120 minutes of testing
95079	Ingestion challenge test (sequential and incremental ingestion of test items, e.g., food, drug, or other substance); each additional 60 minutes of testing (List separately, in addition to code for primary procedure.)
82785	Gammaglobulin (immunoglobulin), IgE
86001 (E/I)	Allergen-specific IgG; quantitative or semiquantitative, each allergen
86003	Allergen-specific IgE; quantitative or semiquantitative, crude allergen extract, each
86005	Allergen-specific IgE; qualitative, multi-allergen screen (e.g., disk, sponge, card)
86008	Allergen-specific IgE; quantitative or semiquantitative, recombinant or purified component, each

Code	Description
86343 (E/I)	Leukocyte histamine release test (LHR)
0165U (E/I)	Peanut allergen-specific quantitative assessment of multiple epitopes using enzyme-linked immunosorbent assay (ELISA), blood, individual epitope results and probability of peanut allergy
0178U (E/I)	Peanut allergen-specific quantitative assessment of multiple epitopes using enzyme-linked immunosorbent assay (ELISA), blood, report of minimum eliciting exposure for a clinical reaction

Not Applicable	

ICD10 Codes

Code	Description
B44.0-B44.9	Aspergillosis (code range)
B48.4	Penicillosis
D80.3	Selective deficiency of immunoglobulin G (IgG) subclasses
D82.0	Wiskott-Aldrich syndrome
H10.411-H10.419	Chronic giant papillary conjunctivitis (code range)
H10.45	Other chronic allergic conjunctivitis
J30.0	Vasomotor rhinitis
J30.1-J30.9	Allergic rhinitis (code range)
J45.20-J45.998	Asthma (code range)
L23.0-L23.9	Allergic contact dermatitis (code range)
L24.0-L24.9	Irritant contact dermatitis (code range)
L25.0-L25.9	Unspecified contact dermatitis (code range)
L27.0-L27.9	Dermatitis due to substances taken internally (code range)

Code	Description
L30.0	Nummular dermatitis
L30.2	Cutaneous autosensitization
L30.8	Other specified dermatitis
L30.9	Dermatitis, unspecified
L50.0	Allergic urticaria
L50.3	Dermatographic urticaria
T36.0X5A-T36.0X5S	Adverse effect of penicillins (code range)
T36.1X5A-T36.1X5S	Adverse effect of cephalosporins and other beta-lactam antibiotics (code range)
T39.015A-T39.015S	Adverse effect of aspirin (code range)
T39.095A-T39.095S	Adverse effect of salicylates (code range)
T63.001A-T63.94XS	Toxic effect of contact with venomous animals and plants (code range)
T65.811A-T65.814S	Toxic effect of latex (code range)
T78.00XA-T78.09XS	Anaphylactic reaction due to food (code range)
T78.2xxA	Anaphylactic shock, unspecified, initial encounter
T78.3xxA	Angioneurotic edema, initial encounter
T78.40XA	Allergy, unspecified, initial encounter
T78.41xA	Arthus phenomenon, initial encounter
T78.49xA	Other allergy, initial encounter
T88.2xxA	Shock due to anesthesia, initial encounter
T88.52XA	Failed moderate sedation during procedure, initial encounter
T88.59xA	Other complications of anesthesia, initial encounter

Code	Description
T88.6XXA	Anaphylactic reaction due to adverse effect of correct drug or medicament properly administered, initial encounter
Z91.010-Z91.09	Allergy status other than drugs & biologicals (code range)

Revised: 07/91, 02/93, 12/94, 10/96, 11/97, 02/98, 03/99, 01/00, 11/00, 10/02, 10/03, 09/04, 11/04, 07/05, 10/06, 05/07, 05/08, 07/08, 07/09, 07/10, 07/11, 07/12, 03/13, 07/13, 01/14, 07/14, 03/15, 07/16, 01/18, 09/18, 7/19, 07/20, 07/21, 9/22, 7/24, 7/25, 9/25, 11/25

Reviewed: 01/92, 08/93, 10/95, 02/00, 06/06, 07/15, 07/17, 07/18, 7/22, 7/23, 9/26

Date	Summary of Changes
9/1/2025	• Removed statement from Policy Considerations regarding 95165 as it is now addressed in payment policy 1550/20.000227, Antigen Preparation for Allergy Immunotherapy.
8/1/2025	• Moved code 86005 from exclusions to In Vitro Allergy Testing section and added additional criteria for in vitro testing.
8/1/2024	• Added a link for NYS DOH August 2016 Medicaid update for immunotherapy to the Select Plan/HARP section.
1/1/2023	• Added statement under Allergy Immunotherapy (code 95165) will be allowed up to a maximum of 150 doses per rolling 12 months. • Under Exclusions added home immunotherapy.

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

11/1/2021	• Removed termed code 95071 from Procedure Codes section. • Added criteria for Skin Endpoint Titration (SET) (95027) and updated when SET would deny in the exclusions section. • Under Policy Considerations added: Periodic skin tests for enrollees should not be repeated unless there is a new condition or for symptomatic/therapeutic reasons. • Under Allergy Immunotherapy removed: Periodic skin tests for enrollees receiving immunotherapy may not be repeated more frequently than every two years, except for a new condition. • Under Exclusions removed: Bronchial thermoplasty for treatment of asthma (31660, 31661) as this procedure is also listed on the Non-Covered Technologies policy as experimental/investigational.
11/1/2020	• Removed termed code 95075 from Procedure Codes section.

MEDICAL POLICY

Medical Policy Title	**Allogeneic Hematopoietic Stem Cell Transplantation (Allo-HSCT)**
Policy Number	**7.02.02**
Current Effective Date	**July 1, 2026**
Next Review Date	**February 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is considered **medically appropriate** when **ALL** of the following are met:

A. Candidates have met the transplanting institution's selection criteria;

B. The multidisciplinary team has evaluated the individual and recommends treatment (see Policy Guidelines for required documentation);

AND

C. The individual is being treated for **ONE (1)** of the following indication-specific criteria, if applicable:

1. Acute Lymphoblastic Leukemia (ALL);
2. Acute Myeloid Leukemia (AML);
3. Chronic Myeloid Leukemia (CML);
4. Chronic Lymphocytic Leukemia (CLL)
5. Non-Hodgkin Lymphoma (B and T-cell Lymphomas);
6. Myelodysplastic Diseases when the following criteria are met:
   a. Disease status is considered intermediate or high risk;
7. Multiple Myeloma;
8. Sickle Cell Anemia, when the following criteria are met:
   a. Children or young adults who have a matched related donor* who are at risk for complications of sickle cell disease who meet **ONE (1)** of the following criteria:
      i. Has experienced an overt stroke, or has an abnormal transcranial doppler ultrasound;

ii. Has frequent pain, and does not respond or have an inadequate response to standard of care treatments (e.g., hydroxyurea, new targeted therapies, chronic transfusion therapies); **or**

iii. Has had recurrent episodes of acute chest syndrome despite standard of care treatment;

*Children or young adults who do not have a matched related donor may be eligible for an unrelated donor transplant in the context of a clinical trial, if there is an indication for HSCT as above.

9. Transfusion-dependent Thalassemia;
10. Bone Marrow Failure Syndromes; including but not limited to:
    a. Acquired Severe Aplastic Anemia;
    b. Fanconi Anemia;
    c. Dyskeratosis Congenita;
    d. Shwachman-Diamond Syndrome;
    e. Diamond-Blackfan Syndrome;
    f. Congenital Amegakaryocytic Thrombocytopenia;
11. Severe/Combined Immunodeficiency and Immune Dysregulation, including but not limited to:
    a. T Cell Immunodeficiency;
    b. Wiskott-Aldrich Syndrome;
    c. Immune dysregulation, Polyendocrinopathy, Enteropathy, X-linked syndrome **(**IPEX) Syndrome;
12. Hemophagocytic Disorders (e.g., Hemophagocytic Lymphohistiocytosis [HLH]);
13. Phagocytic/Innate Immune Cell Disorders, including but not limited to:
    a. Severe Congenital Neutropenia (including Kostmann Syndrome);
    b. Chronic Granulomatous Disease;
    c. Chediak-Higashi Syndrome;
    d. Leukocyte Adhesion Deficiencies;
14. Common Variable Immunodeficiency;
15. Lysosomal/Peroxismal Storage and Leukodystrophy Disorders, including but not limited to:
    a. Mucopolysaccharoidosis I (MPSI, Hurler);

b. Maroteaux-Lamy Syndrome (MPS VI);
c. Gaucher Disease;
d. Globoid Cell Leukodystrophy (Krabbe Disease);
e. Metachromatic Leukodystrophy;
f. Cerebral X-Linked Adrenoleukodystrophy; **or**

16. Skeletal/Metabolic Bone Disorders, including but not limited to:
    a. Osteopetrosis;
    b. Infantile Malignant Osteopetrosis (Albers-Schöberg disease or marble bone disease).

II. Allo-HSCT is considered **investigational** for **ALL** other indications.

RELATED POLICIES

Corporate Medical Policy

7.02.03 Autologous Hematopoietic Stem Cell Transplantation (Auto-HSCT)

7.02.11 Chimeric Antigen Receptor T-cell (CAR-T) Therapy

11.01.03 Experimental or Investigational Services

POLICY GUIDELINE(S)

Recipient Selection Guidelines: Each individual considered for allo- HCT must be evaluated by the transplant center for potential difficulties that would complicate and diminish the success of transplantation. Consideration will be given to the patient's risk of death without transplantation, along with the presence and severity of potential contraindications.

I. Required documentation from the multidisciplinary team that includes the individual's eligibility and risk for autologous stem cell transplant should include:
   A. Clinical Evaluation:
      1. Confirmation of diagnosis;
      2. Identification of comorbidities;
      3. Current assessment of co-morbidities;
      4. Management of co-morbidities;
      5. Consult notes (if applicable);
   B. Psycho-Social Evaluation:
      1. Identification of stressors (e.g., family support, noncompliance issues, motivational issues, alcohol, or smoking/substance abuse);
   C. Performance Status:

1. Karnofsky performance score;
2. Eastern Cooperative Oncology Group (ECOG) performance status,
3. Palliative Performance Scale (PPS) score; or
4. Lansky Play-Performance Scale (for age 1 to 16 years);

D. Oral Health Evaluation;

E. Lab Tests:

1. Complete blood count (CBC), metabolic profile;
2. Serologies: Cytomegalovirus (CMV), Hepatitis B and C;
3. Human Immunodeficiency Virus (HIV) testing;

F. Cardiac Assessment:

1. 12 lead electrocardiogram (EKG);
2. Echochardiogram or multigated acquisition (MUGA) Scan;

G. Pulmonary Assessment:

1. Chest x-ray;
2. Pulmonary function tests (PFTs) for high-risk of respiratory failure (e.g., chronic obstructive pulmonary disease (COPD), emphysema, a-1-antitrypsin deficiency, hepatopulmonary syndrome, or significant smoking history);

H. Age-Appropriate Screening Tests:

Please refer to the U.S Preventive Services Task Force (USPSTF) website for list of age-appropriate screening guidelines: https://www.uspreventiveservicestaskforce.org/uspstf/ [accessed 2026 Jan 19.]

DESCRIPTION

Stem cells differ from other blood cells in that they are capable of both unlimited self-renewal and differentiation to form white blood cells, red blood cells, or platelets. Stem cells can be collected from two sources: direct aspiration of bone marrow or through a pheresis procedure to harvest peripheral blood stem cells (PBSC). Prior to harvesting the stems cells, pretreatment with drugs called "growth factors" or "colony stimulating factors" are given to the donor to enhance stem cell production. The harvested stem cells are then cryopreserved until transplanted.

Hematopoietic stem cell transplantation refers to a procedure that infuses hematopoietic stem cells to restore bone marrow function in cancer patients who receive bone marrow-toxic doses of drugs with or without whole-body radiotherapy.

In allogeneic hematopoietic stem cell (allo-HSCT) transplantation, cells are obtained from a matched related or unrelated donor. The more closely matched the donor to the recipient's tissue type, the

more favorable the outcome for the transplant. Allo-HSCT entails the transfer of an entire hematopoietic system, including a foreign adaptive immune system to a new host. Allo-HSCT is associated with potential complications and benefits. One complication that may develop is graft-vs-host disease (GVHD). In GVHD, the donor cells may attack the recipient tissue which could eventually lead to death. A potential benefit, the graft-vs-tumor effect, arises when the donor cells attack the recipient's tumor tissue. This effect may account for lower relapse rates.

Reduced-intensity conditioning (RIC) refers to chemotherapy regimens that seek to reduce adverse effects secondary to bone marrow toxicity while retaining the beneficial graft-versus-tumor effect of allo-HSCT. These regimens do not eradicate the patient's hematopoietic ability, and allow for relatively prompt hematopoietic recovery (e.g., 28 days or less) even without a transplant. Patients who undergo RIC with allo-HSCT initially demonstrate donor cell engraftment and bone marrow mixed chimerism. Most will subsequently convert to full donor chimerism, which may be supplemented with donor lymphocyte infusions to eradicate residual malignant cells. A number of different cytotoxic regimens, with or without radiotherapy, may be used for RIC allotransplantation.

Myeloablative conditioning (MAC) is the most intense form of conditioning for allo-HSCT and has the greatest risk for regimen-related toxicity. The classic MAC regimen combines myeloablative doses of busulfan with cyclophosphamide and ATG. Commonly referred to as Bu-Cy-ATG, this regimen has been used successfully to treat a broad range of immunodeficiency disorders. MAC agents are expected to produce profound pancytopenia and myeloablation within 1–3 weeks from administration. Pancytopenia is long-lasting, usually irreversible and in most instances fatal, unless hematopoiesis is restored by hemopoietic stem cell infusion.

Acute lymphoblastic leukemia (ALL) is a heterogeneous disease with different genetic variations resulting in distinct biologic subtypes. Patients are stratified to risk-adapted therapy according to certain clinical and genetic risk factors that predict an outcome. Therapy may include HSCT.

Acute myeloid leukemia (AML) refers to leukemias that arise from a myeloid precursor in the bone marrow. AML has a high incidence of relapse, which has prompted research into various post-remission strategies using either allogeneic or autologous HSCT.

Primary refractory acute myeloid leukemia (AML) is defined as leukemia that does not achieve a complete remission after conventionally dosed (non-marrow ablative) chemotherapy.

Chronic Myeloid Leukemia (CML) is a hematopoietic stem cell disorder characterized by the presence of a chromosomal abnormality called the Philadelphia chromosome and predominantly affects older adult males over the age 60. The natural history of the disease consists of an initial (indolent) chronic phase, lasting a median of 3 years, and typically transforms into an accelerated phase, followed by a blast crisis which is usually the terminal event. Most patients present in chronic phase, often with nonspecific symptoms secondary to anemia and splenomegaly. A diagnosis is based on the presence of the Philadelphia chromosome abnormality by routine cytogenetics, or by detection of abnormal BCR-ABL products by fluorescence in situ hybridization or molecular studies, in the setting of persistent unexplained leukocytosis. Conventional dose chemotherapy regimens used for chronic phase disease can induce multiple remissions and delay the onset of blast crisis to a median of 4 to 6 years. However, successive remissions are invariably shorter and more difficult to achieve than their

predecessors. HSCT has shown to be the only curative option.

Chronic lymphocytic leukemia (CLL) and small lymphocytic lymphoma (SLL) are neoplasms of hematopoietic origin characterized by the accumulation of lymphocytes with a mature, generally well-differentiated morphology. In CLL, these cells accumulate in the blood, bone marrow, lymph nodes, and spleen; in SLL they are generally confined to lymph nodes. Chronic lymphocytic leukemia and SLL share many common features and are often referred to as blood and tissue counterparts of each other, respectively. Both tend to present as asymptomatic enlargement of the lymph nodes, tend to be indolent, but can undergo transformation to a more aggressive form of the disease (e.g., Richter transformation). The median age at diagnosis of CLL is approximately 72 years, but it may present in younger individuals, often as a poor-risk disease with significantly reduced life expectancy. The Revised European-American/World Health Organization Classification of Lymphoid Neoplasms considers B-cell CLL and SLL a single disease entity.

Non-Hodgkin's Lymphoma (NHL) is the most common hematological malignancy worldwide (Thandra et al 2021). NHL refers to a diverse class of B-cell and T-cell proliferations. NHL differs from Hodgkin's lymphoma by the clinical characteristics, the absence of Reed-Sternberg cells, and Cd15 and Cd30 staining on histology (Thandra et al 2021). There are over 40 major subtypes, the most common types include follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL). Each type is associated with unique driver genetic mutations (e.g., 14:18 translocation in FL, 11:14 translocation in Mantle Cell, 8:14 in Burkitts lymphoma) and unique risk factors (Epstein–Barr Virus (EBV) for Burkitt's lymphoma, human T-cell lymphoma virus (HTLV-1) for T-cell lymphoma).

NHLs are often divided into two groups, indolent and aggressive depending on the types of affected cells and the rate of growth of the cells. Indolent Non-Hodgkin Lymphomas (NHLs) tend to grow and spread slowly with few symptoms. They are low-grade cancers which are often very responsive to treatments like chemotherapy, radiation, and immunotherapy. However, treatment is often deferred until the patient becomes symptomatic. The goal of treatment is often management as indolent lymphomas are rarely cured unless it is diagnosed when still localized. Thus, treatment options are more varied with no standardization. NHLs are fast growing and are described as intermediate or high grade. They can be treated with chemotherapy, radiotherapy, monoclonal antibody therapy, or a combination. The decision on the exact course of treatment is usually dependent on a number of factors such as, the stage of the disease, the number of nodes involved, the presence of lymphoma in other organs, and age.

Tandem transplants usually are defined as the planned administration of two successive cycles of high dose myeloablative chemotherapy, each followed by infusion of autologous hematopoietic stem cells, whether or not there is evidence of persistent disease following the first treatment cycle. Sometimes, the second cycle may use nonmyeloablative immunosuppressive conditioning followed by infusion of allogeneic stem cells.

The term salvage therapy describes therapy given to patients with refractory or relapsed disease. For patients with peripheral T-cell lymphoma, salvage therapy includes patients who do not achieve a complete response (e.g., achieve only a partial response, have no response, or have progressive disease) with first-line induction chemotherapy (refractory disease) or who relapse after achieving a

complete response with first-line induction chemotherapy.

Sickle cell disease (SCD) is the most common inherited hemoglobinopathy in the United States. In SCD, the shape of the red blood cells is affected and have a sickle or crescent moon appearance. This abnormal shape can cause blood flow disruption or a total blockage. SCD is characterized by continuous intravascular hemolysis and microvascular occlusion resulting in recurrent vaso-occlusive painful events and severe organ complications (Aydin et al 2021). SCD symptoms can begin to show when a child is about 5 to 6 months of age and can result in significant morbidities and early mortality.

Acute chest syndrome (ACS) is a complication of SCD, and it can cause chest pain, cough, fever, low oxygen levels, and cause injury to the lungs. ACS syndrome is the leading cause of hospitalization and death in people with sickle cell disease. Hematopoietic stem cell transplantation (HSCT) is currently the only established curative intervention for SCD that can restore normal hematopoiesis.

High-risk T-cell and natural killer cell neoplasms are a clinically heterogeneous group of rare disorders, most of which have an aggressive clinical course and poor prognosis. The exception includes the following subtypes, which typically have a relatively indolent and protracted course (T-cell large granulocyte leukemia, chronic lymphoproliferative disorder of natural killer cells, early-stage mycosis fungoides, primary cutaneous anaplastic large-cell lymphoma, and anaplastic lymphoma kinase-anaplastic large-cell lymphomas).

Myelodysplastic syndromes (MDS) and myeloproliferative neoplasms refer to a heterogeneous group of clonal hematopoietic disorders with the potential to transform into acute myelocytic leukemia. Allo-HSCT has been proposed as a curative treatment option for patients with these disorders (Saber and Horowitz 2016).

Myeloid neoplasms are categorized according to criteria developed by the World Health Organization (WHO). Neoplasms are risk-stratified using the International Prognostic Scoring System (IPSS).

Disability Scores

I. The Karnofsky performance status score describes a patient's functional status as a comprehensive 11-point scale correlating to percentage values ranging from 100% (no evidence of disease, no symptoms) to 0% (death). Adapted from Peus et al 2013:

A: Able to carry on normal activity and to work. No special care is needed.	100	Normal, no complaints, no evidence of disease.
	90	Able to carry on normal activity, minor signs or symptoms of disease.
	80	Normal activity with effort, some signs, or symptoms of disease.
B: Unable to work. Able to live at home, care for most personal needs.	70	Cares for self, unable to carry on normal activity or to do active work.

A varying degree of assistance is needed.	60	Requires occasional assistance but is able to care for most of personal needs.
	50	Requires considerable assistance and frequent medical care.
C: Unable to care for self. Requires equivalent of institutional or hospital care. Disease may be progressing rapidly.	40	Disabled, requires special care and assistance. [In bed more than 50% of the time]
	30	Severely disabled, hospitalization is indicated although death not imminent. [Almost completely bedfast]
	20	Very ill, hospitalization and active supportive treatment necessary. [Totally bedfast and requiring extensive nursing care by professionals and/or family]
	10	Moribund, fatal processes progressing rapidly. [Comatose or barely arousable]
	0	Dead.

II. Palliative Performance Scale (PPS) score; adapted from Fast Facts and Concepts (Wilner and Arnold 2006):

Percentage	Ambulation	Activity Level/Evidence of Disease	Self-Care	Intake	III. Level of Consciousness
100	Full	Normal No Disease	Full	Normal	Full
90	Full	Normal Some Disease	Full	Normal	Full
80	Full	Normal with Effort Some Disease	Full	Normal or reduced	Full
70	Reduced	Can't do normal job or work.	Full	As above	Full

		Some Disease			
60	Reduced	Can't do hobbies or housework. Significant Disease	Occasional Assistance Needed	As above	Full or confusion
50	Mainly sit/lie	Can't do any work. Extensive Disease	Considerable Assistance Needed	As above	Full or Confusion
40	Mainly in bed	As above	Mainly Assistance	As above	Full or Drowsy or Confusion
30	Bed Bound	As above	Total Care	Reduced	As above
20	Bed Bound	As above	As above	Minimal	As above
10	Bed Bound	As above	As above	Mouth care only	Drowsy or coma
0	Death	-	-	-	-

III. Eastern Cooperative Oncology Group (ECOG) performance status; adapted from ECOG-ACRIN Cancer Research group:

Grade	ECOG PERFORMANCE STATUS
0	Fully active, able to carry on all pre-disease performance without restriction
1	Restricted in physically strenuous activity but ambulatory and able to carry out work of a light or sedentary nature, e.g., light housework, office work
2	Ambulatory and capable of all selfcare but unable to carry out any work activities; up and about more than 50% of waking hours
3	Capable of only limited selfcare; confined to bed or chair more than 50% of waking hours
4	Completely disabled; cannot carry on any selfcare; totally confined to bed or chair
5	Dead

IV. Lansky Play-Performance Scale (for age 1 to 16 years)

The Lansky play-performance scale is used for children aged 1-16 with any type of malignancy. It is

typically rated by parents based on their child's activity over the past week. Adapted from: Performance status | HemOnc.org - A Hematology Oncology Wiki [accessed 2025 Nov 24]:

Rating	Description
100	Fully active, normal
90	Minor restrictions with strenuous physical activity
80	Active, but gets tired quickly
70	Both greater restriction of, and less time spent in, active play
60	Up and around, but minimal active play; keeps busy with quieter activities
50	Lying around much of the day, but gets dressed; no active play; participates in all quiet play activities
40	Mostly in bed; participates in quiet activities
30	Stuck in bed; needs help even for quiet play
20	Often sleeping; play is entirely limited to very passive activities
10	Does not play or get out of bed
0	Unresponsive

SUPPORTIVE LITERATURE

Masetti et al (2022) conducted a meta-analysis of allo-HSCT for pediatric patients with AML in first complete response. Both prospective and retrospective studies comparing allo-HSCT to chemotherapy in higher-risk patients were considered. A total of 9 studies (5 prospective, 4 retrospective) were included. None of the prospective studies were randomized. The meta-analysis showed that overall survival (OS) was improved with allo-HSCT compared with chemotherapy. Similarly, disease-free survival (DFS) was improved compared to chemotherapy. Risk of relapse was higher among patients who received chemotherapy.

Huang and colleagues (2025) performed a cross-study analysis of two-phase III Children's Oncology Group clinical trials to evaluate whether hematopoietic stem cell transplantation (HSCT) improves outcomes for pediatric patients with high-risk acute myeloid leukemia (AML). They compared patients who received HSCT in first complete remission (CR1) with those treated with chemotherapy alone in CR1. The analysis included 463 patients with high-risk cytogenetic or molecular features and 72 patients with standard-risk features who had positive measurable residual disease (MRD) after the first induction cycle. Among these groups, 33.9% of high-risk patients and 45.8% of standard-risk

patients underwent HSCT in CR1. Across both risk groups, HSCT was associated with lower relapse rates and improved disease-free survival (DFS). In the high-risk cohort, 5-year DFS was 26% for patients treated with chemotherapy alone, compared with 49.8% for those who received both chemotherapy and HSCT. Similarly, in the standard-risk cohort, 5-year DFS was 16.9% with chemotherapy alone versus 50.9% for those who underwent HSCT. Overall, the authors concluded that HSCT in CR1 is associated with significantly improved outcomes for pediatric patients with high-risk AML.

Barge et al (2025) aimed to examine the use of Allo-HSCT in the modern era of chronic lymphocytic leukemia (CLL) treatment by collecting data from the Australian and New Zealand Transplant and Cellular Therapy Registry for all patients who underwent HSCT for CLL between January 2009 and December 2018. Outcomes were compared between two periods of time, 2009-2013 (n=94) vs. 2014-2018 (n=50) and included patients who were treated with pathway inhibitors prior to transplant, which was more likely for those patients treated in the later cohort. Authors reviewed median time to engraftment, incidence of graft vs host disease, cytomegalovirus reactivation, survival, and cause of death. The median time to neutrophil engraftment for the 2009-2013 cohort was 16 days, and 17 days for the 2014-2018, while median platelet engraftment occurred at 19 and 16 days for the 2009-2013 and 2014-2018 cohorts, respectively. The cumulative incidence of graft versus host disease at 100 days was less for the later cohort at 33% vs. 52% for 2009-2013 with similar differences seen at 5 years. At the follow up time frame of 7.6 years for 2009-2013 cohort and 5.0 years for the 2014-2018 cohorts, there were no differences in OS, progression free survival (PFS), reported cause of death or relapse, but there was a significant improvement in non-relapse mortality from 42% to 23% in the later cohort. Authors concluded that allo-HSCT remains a viable treatment option for select patients with CLL.

Allo-HSCT is an established curative treatment option for patients with sickle cell disease (SCD). The pediatric population has primarily been the focus of published data. Studies have shown that allo-HSCT, if performed before the age of 10 are associated with reduced mortality and lower health care costs (Iqbal et al 2021). There are few studies that evaluate the efficacy of allo-HSCT for adults.

Recently an international effort on behalf of the pediatric diseases working party of European Society for blood and bone marrow transplantation and sickle cell disease transplantation international consortium conducted a systematic review and meta-analysis on the efficacy of allo-HSCT for the treatment of sickle cell disease. There were 33 studies representing 2853 patients who met inclusion criteria. Data was collected on patients undergoing allo-HSCT between 1986 and 2017 who had recurrent vaso-occlusive crisis, acute chest syndrome, and stroke. The majority of patients had multiple indications, but the most common indication was for vaso occlusive crisis. A matched related sibling was the most common donor source, and bone marrow was the most common hematopoietic cell source. All groups (both adults and pediatric) had an OS rate of 96%, DFS 90%, acute graft versus host disease (aGVHD) of 20%, chronic graft versus host disease (cGVHD) of 10%, nonrelapse mortality of 4% and graft failure of 5% (Iqbal et al 2021).

Du et al (2023) performed a systematic review and meta-analysis on transplant for refractory or relapsed peripheral T cell-lymphoma (R/R-PTCL) and reported outcomes of allo-HSCT and autologous HSCT for R/R-PTCL. Individuals in the two groups had similar survival rates, as opposed to individuals

with R/R-PTCL who underwent autologous HSCT had fewer adverse events than those who underwent allogeneic HSCT. Per researchers this could possibly be due to GVHD counterbalances the accompanying graft versus lymphoma effect after allogeneic HSCT. In considering the pretransplant status, most patients in the allogeneic HSCT group were insensitive to chemotherapy, and allogeneic HSCT served as a salvage therapy, which provided an additional survival advantage for patients with R/R-PTCL. The findings of this study suggest that, overall, HSCT is an effective therapy for R/R-PTCL. Individuals with R/R-PTCL with lower-risk stratification might prefer autologous HSCT, although allo-HSCT can still serve as a salvage therapy in those with a higher-risk disease stage.

PROFESSIONAL GUIDELINE(S)

In 2020, the American Society of Transplantation and Cellular Therapy (ASTCT) convened a guideline committee to make recommendations for the use of hematopoietic cell transplantation and immune effector cell therapy. Indications were categorized as (1) Standard of care, where indication is well defined and supported by evidence; (2) Standard of care, clinical evidence available, where large clinical trials and observational studies are not available but have shown to be effective therapy; (3) Standard of care, rare indication, for rare diseases where demonstrated effectiveness exists but large clinical trials and observational studies are not feasible; (4) Developmental, for diseases where preclinical or early-phase clinical studies show promising results, and (5) not generally recommended, where available evidence does not support the routine use of hematopoietic stem cell transplantation. For updated guidelines, visit: https://www.guidelinecentral.com/guideline/26026/#section-336178 [accessed 2026 Jan 19].

Following the ASTCT guideline recommendations, several indication specific guidelines have been published, including:

- Newly Diagnosed Adult Acute AML (Dholaria et al 2021);
- Pediatric Acute AML and Myelodysplastic Syndromes (Tarlock et al 2022);
- Follicular Lymphoma (a collaborative effort on behalf of ASTCT and the European Society for Blood and Marrow Transplantation (Iqbal et al 2024);
- Severe Aplastic Anemia (Iftikhar et al 2024);
- Mycosis Fungoides and Sézary Syndrome (a joint recommendation with the United States Cutaneous Lymphoma Consortium [USCLC]) (Goyal et al 2024);
- Diffuse Large B Cell Lymphoma (Epperla et al 2023);
- Classical Hodgkin Lymphoma (Pre-proof, Ahmed et al 2025);
- Evaluation of Children with Malignancies for Blood and Marrow Transplantation (Fraint et al 2023);

In 2020, the European Society for Medical Oncology (ESMO) published clinical practice guidelines for the diagnosis, treatment, and follow up of chronic lymphocytic leukemia (CLL) (Eichhorst et al) that are endorsed by the European Hematology Association (EHA) through the Scientific Working Group on CLL/European research initiative on CLL (ERIC). The panel recommended that patients who are

refractory to chemoimmunotherapy with TP53 mutation or del(17p), but fully responsive to novel inhibitor therapy; patients refractory to chemoimmunotherapy and to novel inhibitor therapy, even those with a higher risk of non-relapse mortality (evidence level III,B), as well as patients with Richter's transformation in remission after therapy and clonally related to CLL.

In 2021, Kanter and colleagues published clinical guidelines for sickle cell disease (SCD): stem cell transplantation on behalf of the American Society of Hematology (ASH). The review of the evidence conducted by the panel yielded no randomized controlled trials, with all recommendations being made based upon very low certainty in the evidence and resulting in a recommendation for the development of a robust SCD registry to serve as a comparator for future HSCT studies. The conditional recommendations were as follows:

- "The ASH guideline panel suggests HLA-matched related HSCT rather than standard of care (hydroxyurea (H/U)/transfusion) in patients with SCD who have experienced an overt stroke or have an abnormal transcranial Doppler ultrasound;
- For patients with frequent pain, the ASH guideline panel suggests using related matched allogeneic transplantation rather than standard of care;
- For patients with recurrent episodes of acute chest syndrome (ACS), the ASH guideline panel suggests using related allogeneic transplantation over standard of care;
- For patients with SCD with an indication for HSCT who lack an MSD, the ASH guideline panel suggests using transplants from alternative donors in the context of a clinical trial;
- For allogeneic HSCT, the ASH guideline panel suggests using either total-body irradiation (TBI) #400 cGy or chemotherapy-based conditioning regimens.
- For children with SCD who have an indication for allogeneic HSCT and an MSD, the ASH guideline panel suggests using myeloablative conditioning over RIC that contains melphalan/fludarabine regimens;
- For adults with SCD who have an indication for allogeneic HSCT and an MSD, the ASH guideline panel suggests nonmyeloablative conditioning over RIC that contains melphalan/fludarabine regimens;
- In patients with an indication eligible for HSCT, the ASH guideline panel suggests using allogeneic transplantation at an earlier age rather than an older age;
- The ASH guideline panel suggests the use of HLA-identical sibling cord blood when available (and associated with an adequate cord blood cell dose and good viability) over bone marrow (BM)"

In 2023, Fraint and colleagues published a report from the ASTCT Committee on practice guidelines for the evaluation of children with malignancies for blood and marrow transplantation. ASTCT states, "Children with malignancy who require HCT for cure have a unique set of psychosocial needs, physical comorbidities, and disease risk features that differentiate them from adults. Given the inability for some of the important pre-HCT risk indices developed for adults to be applied to children, a specialized approach is needed, ideally with harmonization among centers." Although rigorous data

on physiologic differences and randomized trials on management are lacking for children, the recommendations provided are meant to serve as a guide for pre-HCT preparations.

In 2025, Damaj et al published recommendations from the European Society for Blood and Marrow Transplantation (EBMT) Practice Harmonisation and Guidelines Committee for allogeneic hematopoietic cell transplantation in peripheral T-cell lymphoma. Recommendations included:

- "Allogeneic HCT is the treatment of choice in patients with insufficient response or refractory to first-line therapy; and with relapsed disease after first complete response regardless of prior treatment, including autologous HCT;
- Eligibility for allogeneic HCT should be established early, donor search should be initiated as soon as no response to first-line treatment becomes obvious; proceed to allogeneic HCT, regardless of result of salvage therapy, as long as transplant eligibility is retained;
- There is no strict age limit for allogeneic HCT; age should be evaluated in context of other risk factors, candidates with a HCT comorbidity Index (HCT-CI) score of 2 or less with good performance status are most suitable for allogeneic HCT; however these factors must be considered together with age, comorbidities, and disease status to determine the overall risks of allogeneic HCT;
- Although patients in complete remission have the best outcomes after allogeneic HCT, patients in partial remission should also proceed directly to allogeneic HCT; Patients with stable or progressive disease can expect a probability of long-term survival and thus should be considered for allogeneic HCT, if eligible, on an individual basis;
- The preferred donor hierarchy is in the order: matched sibling donor, matched unrelated donor, haploidentical donor, mismatched unrelated donor; both peripheral blood stem cells and bone marrow are acceptable graft sources.

The National Comprehensive Cancer Network (NCCN) V.1.2026 Guidelines for B-Cell Lymphomas recommend consolidation with allo-HCT in patients with relapsed/refractory mantle cell lymphoma that is in remission following second-line therapy with fixed-duration regiments, additionally for those patients with MCL that is refractory to or progressing on second-line subsequent therapy and for disease relapse or progressive disease following CAR T-cell therapy.

NCCN V.5.2026 Guidelines for Multiple Myeloma identifies the potential use of allo-HCT given the lack of significant cure rate for single or tandem autologous HCT, for those individuals with multiple myeloma as initial therapy or as therapy for relapsed or refractory disease.

NCCN V.1.2026 Guidelines for Pediatric Acute Lymphoblastic Leukemia recommends the use of allo-HCT in those with persistent disease, or disease with high-risk features (KMT2A rearrangements) based on limited data available, stating it is "reasonable to consider HCT in first remission for certain patients."

NCCN V.2.2025 Guidelines for Acute Lymphoblastic Leukemia acknowledge that allo-HCT is more likely to be a utilized treatment in adult patients with evidence of high-risk features (Ph-like disease, or persistent measurable residual disease) and in post consolidative therapy in adolescents and

young adults, and therefore recommend that, "HLA typing and bone marrow transplant referral should be considered for all patients with newly diagnosed disease and patients with relapsed disease who have not yet undergone transplant to facilitate timely donor identification, and ultimately allogeneic transplant if warranted.

NCCN V.2.2026 Guidelines for Acute Myeloid Leukemia (AML), allo-HCT can be considered an option for individuals with intermediate-risk and poor-risk AML in those who have already achieved remission and have a donor available.

NCCN V.1.2026 Guidelines for T-Cell Lymphomas recommend that allo-HCT can be a treatment option for patients who achieve a complete or partial response after initial therapy and also acknowledge that given the poor prognosis associated with T-cell prolymphocytic leukemia, patients should be enrolled in a clinical trial.

NCCN V.3.2025 Guidelines for Waldenstrom Macroblobulinemia/Lymphoplasmacytic Lymphoma recommend that myeloablative or non-myeloablative allo-HSCT be considered only within the context of a clinical trial.

REGULATORY STATUS

The U.S. Food and Drug Administration (FDA) regulates vaccines, blood, and blood products (including hematopoietic stem cells), and biologics via the Center for Biologics Evaluation and Research (CBER) which ensures the safety, efficacy, and quality of these products. Refer to the FDA vaccines/blood/biologics website. Available from: https://www.fda.gov/vaccines-blood-biologics [accessed 2026 Jan 21]

The FDA maintains information for consumers and health professionals on vaccine, blood and biologics warnings and other safety information. Available from: https://www.fda.gov/vaccines-blood-biologics/safety-availability-biologics/recalls-biologics [accessed 2026 Jan 21]

Code	Description
38205	Blood-derived hematopoietic progenitor cell harvesting for transplantation, per collection; allogeneic
38210	Transplant preparation of hematopoietic progenitor cells; specific cell depletion within harvest, T-cell depletion

Code	Description
38212	Transplant preparation of hematopoietic progenitor cells; red blood cell removal
38213	Transplant preparation of hematopoietic progenitor cells; platelet depletion
38230	Bone marrow harvesting for transplantation, allogeneic
38240	Hematopoietic progenitor cell (HPC); allogeneic transplantation per donor
38242	Allogeneic lymphocyte infusions
38243	Hematopoietic progenitor cell (HPC); HPC boost

Copyright © 2026 American Medical Association, Chicago, IL

HCPCS Codes

Code	Description
S2142	Cord blood-derived stem-cell transplantation, allogeneic
S2150	Bone marrow or blood-derived stem cells (peripheral or umbilical), allogeneic or autologous, harvesting, transplantation, and related complications; including: pheresis and cell preparation/storage; marrow ablative therapy; drugs, supplies, hospitalization with outpatient follow-up; medical/surgical, diagnostic, emergency, and rehabilitative services; and the number of days of pre- and posttransplant care in the global definition

ICD10 Codes

Code	Description
C26.0-C26.9	Malignant neoplasm of other and ill-defined digestive organs (code range)
C33	Malignant neoplasm of trachea
C34.00-C34.92	Malignant neoplasm of bronchus and lung (code range)
C38.1-C38.8	Malignant neoplasm of mediastinum and pleura (code range)
C47.0-C47.9	Malignant neoplasm of peripheral nerves and autonomic nervous system (code range)
C48.0	Malignant neoplasm of retroperitoneum
C49.0-C49.9	Malignant neoplasm of other connective and soft tissue (code range)
C50.011-C50.919	Malignant neoplasm of breast (code range)

Code	Description
C62.00-C62.92	Malignant neoplasm of testis (code range)
C71.0-C71.9	Malignant neoplasm of brain (code range)
C81.00-C81.99	Hodgkin lymphoma (code range)
C82.00-C82.59	Follicular lymphoma (code range)
C82.60-C82.99	Cutaneous follicle center lymphoma
C83.00-C83.99	Non-follicular lymphoma (code range)
C84.60-C84.79	Anaplastic large cell lymphoma, ALK-positive or ALK-negative (code range)
C86.5	Angioimmunoblastic T-cell lymphoma
C86.6	Primary cutaneous CD30-positive T-cell proliferations
C88.2-C88.9	Malignant immunoproliferative diseases and certain other B-cell lymphomas (code range)
C90.00-C90.32	Multiple myeloma and malignant plasma cell neoplasms (code range)
C91.10-C91.12	Chronic lymphocytic leukemia of B-cell type (code range)
C94.40-C94.42	Acute panmyelosis with myelofibrosis (code range)
C94.6	Myelodysplastic disease, not classified
D46.0-D46.9	Myelodysplastic syndromes (code range)
D46.A-D46.Z	Refractory cytopenia with multilineage dysplasia (code range)
D47.1	Chronic myeloproliferative disease
D47.3	Essential (hemorrhagic) thrombocythemia
D47.9	Neoplasm of uncertain behavior of lymphoid, hematopoietic and related tissue, unspecified

Code	Description
D47.Z1	Post-transplant lymphoproliferative disorder (PTLD)
D47.Z9	Other specified neoplasms of uncertain behavior of lymphoid, hematopoietic and related tissue
D56.0-D56.9	Thalassemia (code range)
D57.00-D57.819	Sickle-cell disorders (code range)
D60.0-D61.9	Acquired pure red cell aplasia [erythroblastopenia] (code range)
D81.0-D82.0	Combined immunodeficiencies (code range)
E75.21-E75.3	Other sphingolipidosis (code range)
E76.01-E76.03	Disorders of glycosaminoglycan metabolism (code range)
E77.0-E77.9	Disorders of glycoprotein metabolism (code range)
G35	Multiple sclerosis
M32.0-M32.9	Systemic lupus erythematosus (SLE) (code range)
M34.0-M34.9	Systemic sclerosis [scleroderma] (code range)

PRODUCT DISCLAIMER

- Services are contract dependent; if a product does not cover a service, medical policy criteria do

not apply.

- If a commercial product (including an Essential Plan or Child Health Plus product) covers a specific service, medical policy criteria apply to the benefit.
- If a Medicaid product covers a specific service, and there are no New York State Medicaid guidelines (eMedNY) criteria, medical policy criteria apply to the benefit.
- If a Medicare product covers a specific service, and there is no national or local Medicare coverage decision for the service, medical policy criteria apply to the benefit.

Policy/Procedure Name: Alpha$_1$-Proteinase Inhibitors (Human) **Control Number: 1350/20.000310**

Disclaimer Notice

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgment when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

Background

Alpha$_1$-antitrypsin (AAT), or alpha 1 proteinase inhibitor, is a protein that is made by the liver whose main function in the body is to protect tissues from being damaged due to proteolytic enzymes, especially neutrophil elastase (NE). Alpha$_1$-antitrypsin deficiency is a hereditary, autosomal recessive disorder that can increase the risk of lifelong complication in patients with the genetic disorder. The *SERPINA1* gene encodes for the AAT protein and it has several alleles that account for the different levels of function the resulting protein will possess. The most common, normal allele of the proteinase inhibitor (PI) is the *PI*M* variant. The *PI*Z* variant is the most common pathogenic allele that is a stronger indicator that a patient may have an increased risk of a clinical deficiency. The two other more common variants include the *PI*S* allele that results in a functionally deficient protein and the *PI*null* allele that results in either no mRNA or no protein. Patients with AAT deficiency are at an increased risk of developing liver and lung disease due to an inability to prevent inflammation to these tissues. The most common patient presentation includes emphysema.

There are four medications that are currently Food and Drug Administration (FDA)-approved for the treatment of AAT deficiency: Prolastin-C®, Aralast NP®, Zemaira®, and Glassia®. All of the medications are made with purified human alpha$_1$-proteinase inhibitors. These medications help to inhibit NE, therefore increasing protection against damage in the lung tissues.

Summary

Effective Date of Policy	5-1-2018
Indications	Emphysema due to alpha$_1$-antitrypsin (AAT) deficiency
ICD10 Diagnosis Codes	E88.01 – Alpha$_1$-antitrypsin deficiency
Availability	Prolastin-C 1,000mg, 20mL solution for inj Aralast NP 1,000mg, 50mL solution for inj, 500mg powder for injection, 25mL solution for inj Zemaira 1,000mg, 4000mg and 5000mg powder for injection, 20mL, 76mL, 95mL solution for inj Glassia 1,000mg, 50mL solution for inj
HCPCS codes	Prolastin C: J0256; Glassia: J0257; Aralast: J0256; Zemaira: J0256
Limitations	Alpha$_1$-Proteinase Inhibitors cannot be approved for those with a non-approved mutations
Duration	Initial approval: six months Continuation approval: six months

Required Criteria for Initial Approval		
All of the following conditions for the requested indication must be met in order to approve Alpha$_1$-Proteinase Inhibitors (Human):		
Indication	**Inclusion**	**Exclusion**
Alpha$_1$-Antitrypsin Deficiency (FDA approval) ICD 10: E88.01	1. The enrollee has a diagnosis of alpha$_1$-antitrypsin (AAT) deficiency **AND** 2. The enrollee is 18 years of age or older **AND** 3. Medication must be prescribed by a pulmonologist with expertise in treatment of AAT deficiency **AND** 4. There is a confirmed mutation of PI*SZ, PI*ZZ, PI*Z-null, or PI*null-null **AND** 5. Member has a serum AAT level <57mg/dL by nephelometry **AND** 6. Member has clinical evidence of emphysema **AND** 7. Patient must be a current non-smoker, which may include documentation of a negative cotinine urine test at the discretion of the provider	Medications will NOT be approved: • For members who are active smokers • In heterozygote mutations that include a normal (*PI*M*) allele or a homozygous mutation of *PI*SS* • Any contraindications to treatment are present
Approved Dosing	• All medications are to be dosed at 60mg/kg IV infusion once weekly	
Continuation Criteria		
Continue current approval for Alpha$_1$-Proteinase Inhibitors (Human) if following criteria is met:		
	1. The enrollee still meets the inclusion criteria listed above **AND** 2. Member is tolerating therapy without signs of unacceptable drug toxicity during previous treatment with these medications	

Considerations

- Requests for off-label indications or dosing of Alpha$_1$-Proteinase Inhibitors (Human) will be reviewed on a case-by-case basis using the criteria established in pharmacy policy: *Off-Label Uses of FDA Approved Drugs, control #1350/20.000048.*
- CDPHP reserves the right to make decisions based on clinical judgment on a case-by-case basis.
- For Medicare members utilizing these therapies within the prescription benefit, refer to policy 1350/20.000278.

MEDICAL POLICY

Medical Policy Title	**Ambulance: Air**
Policy Number	**11.01.06**
Current Effective Date	**September 1, 2026**
Next Review Date	**March 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service.
(Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Air ambulance transportation services may be determined to be **medically appropriate** only to the nearest facility that can provide the appropriate care when **ALL** of the following criteria are met:

   A. The individual's medical condition, required immediate and rapid ambulance transportation that was necessary to minimize risk of death or deterioration of the individual's condition and that could not have been provided by land ambulance and **either** of the following indications;

      1. The point of pick-up is inaccessible by land vehicle;
      2. Great distances or other obstacles (e.g., traffic, weather conditions) would impact getting the individual to the nearest hospital with appropriate facilities, if the individual were to be transported via land/ground ambulance.

Hospital-to-Hospital Air Transport

II. Hospital-to-hospital air ambulance transportation is considered **medically appropriate** when **BOTH** of the following are met:

   A. Transferring an individual to a higher level of care hospital to provide medical services that are unavailable at the transferring facility;

   B. Ground ambulance would endanger the individual's health.

III. Hospital-to-hospital air ambulance transportation services are considered **not medically appropriate** for **EITHER** of the following indications:

   A. Transportation to a non-acute care facility;

   B. Non-emergent transportation of a stabilized individual.

Corporate Medical Policy

10.01.07 Land/Ground Ambulance Services

Clinical Review Preauthorization List

POLICY GUIDELINE(S)

I. Air ambulance transportation services are contract specific. Please refer to the member's subscriber contract for limitations and/or exclusions. Some contracts may:

   A. Exclude air ambulance transportation services or limit transportation distances; or

   B. Require air ambulance claims to be accompanied by a Pre-Hospital Care Report.

II. Benefits are not available for elective or convenience air ambulance transportation.

III. Air ambulance services may be **eligible for coverage** based on the time of death pronouncement of the individual in the following scenarios:

   A. After takeoff to the point-of-pickup (POP) and before the individual is loaded on board the air ambulance; or

   B. After the individual is loaded on board the air ambulance and before or upon arrival at the receiving facility.

IV. Air ambulance service is **ineligible for coverage** if the individual is pronounced dead before the ambulance is dispatched.

V. Prior authorization for interfacility transfer is contract-dependent, authorization must be obtained prior to transfer of the individual.

VI. If the member's subscriber contract requires prior authorization for inpatient admissions, prior authorization is required to accept a transfer of a registered inpatient from another facility through the emergency department.

VII. Examples of emergency situations that can be considered for air ambulance transfer:

   A. In obstetric individuals, air transport's advantage of minimized out-of-hospital time must be balanced against the risks inherent to land transport delivery. If transport is necessary for a patient whose delivery is thought to be imminent, then a ground vehicle is most often the preferred mode of transport. Air transport may be considered in the rare circumstances when ground transport is logistically not feasible and/or there are circumstances, including but not limited to, the following:

      1. Active premature labor with contractions resulting in progressive effacement and dilation of the cervix when estimated gestational age is less than 34 weeks or estimated fetal weight is less than 2,000 grams;

      2. Severe pre-eclampsia or eclampsia;

      3. Third-trimester hemorrhage;

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

4. Fetal hydrops; or
5. Acute abdominal emergencies (e.g., likely to require surgery) when estimated gestational age is less than 34 weeks or estimated fetal weight is less than 2,000 grams;

B. Transplant candidates with end-stage organ disease when they have all of the following indications:

1. The candidate is on the waiting list for organ transplantation;
2. The organ to be transplanted has been procured;
3. The transplant is imminent; and
4. Organ preservation times are critical (e.g., heart or lung).

VIII. Examples of individuals for whom hospital-to-hospital air transport (e.g., emergency room to tertiary care facility) may be considered for the following indications, including, but are not limited to:

A. Individuals with dissecting aortic aneurysms, who are receiving intravenous pressor drug titration or invasive monitoring;

B. Individuals with unstable vital signs, who require enroute pharmacologic interventions that would not be available or medically advisable by ground transport; or

C. Transplantation individuals who are unable to tolerate prolonged out-of-hospital times or who have acute organ rejection.

DESCRIPTION

Ambulance services involve the assessment and administration of care to the ill or injured individual by specially trained personnel and the transportation of the individual in specially designed and equipped vehicles within an appropriate, safe, and monitored environment. Ambulance services are frequently the initial step in the chain of the delivery of medical care. This policy only addresses those ambulance services rendered by an air ambulance.

Air ambulance transportation services are provided by fixed (plane) or rotary (helicopter) wing equipment.

<u>Air ambulance transport may involve</u>

- The emergency transportation of an individual to the nearest hospital with the appropriate facilities for the treatment of the individual's illness or injury; or
- The non-emergent medical transport of a registered hospital inpatient to another location to obtain medically necessary, specialized diagnostic or therapeutic services.

<u>Ambulance Services are rendered for Emergent, Urgent or Non-Emergent Reasons</u>

- Emergent services are defined as services for a medical or behavioral condition with acute symptoms of sufficient severity that the absence of immediate medical attention would result in

placing the health of the individual in serious jeopardy, serious impairment of bodily function or serious dysfunction of any body organ or part. In the case of a behavioral condition, lack of immediate medical attention may also place the health of others in serious jeopardy.

- Urgent services are defined as services for a medical or behavioral condition that require immediate attention, although the condition may not be an emergency situation. An urgent care condition has the potential to become emergent in the absence of treatment.
- Non-emergent services are defined as services for a medical or behavioral condition that are not considered to be of an emergent or urgent nature (e.g., elective surgery).

Examples of individuals who may qualify for hospital-to-hospital air transport (e.g., emergency room to tertiary care facility) include, but are not limited to:

- Individuals with dissecting aortic aneurysms, who are receiving intravenous pressor drug titration or invasive monitoring;
- Individuals with unstable vital signs, who require enroute pharmacologic interventions that would not be available or medically advisable by ground transport; or
- Transplantation individuals who are unable to tolerate prolonged out-of-hospital times or who have acute organ rejection.

SUPPORTIVE LITERATURE

Not Applicable

PROFESSIONAL GUIDELINES

National Association of Emergency Medical Service Physicians (NAEMSP) states that some conditions (e.g., flail chest) can be clearly diagnosed in the field, while others (e.g., suspected cardiac injury or findings) requiring providers to act on clinical judgement. Air transport is generally indicated when it enables faster arrival to the appropriate facility or quicker access to advanced care by the helicopter crew. This position statement has been endorsed by the Air Medical Physician Association (AMPA).

According to the NAEMSP Guidelines for Air Medical Dispatch (Thomson et al 2003), the following are the indicated clinical situations for triage to air transport at the scene of an emergency:

<u>Trauma</u>

Scene response to injured patients probably represents the mode of helicopter utilization with the best supporting evidence.

- General and mechanism considerations:
  - Trauma score less than 12 (Glasgow Coma Scale, Systolic Blood Pressure, Respiratory);
  - Unstable vital signs (e.g., hypotension or tachypnea);
  - Significant trauma in patients less than 12 years old, greater than 55 years old, or pregnant;

- Multisystem injuries (e.g., long-bone fractures in different extremities; injury to more than two body regions);
- Ejection from vehicle;
- Pedestrian or cyclist struck by motor vehicle;
- Death in same passenger compartment as patient;
- Ground provider perception of significant damage to patient's passenger compartment;
- Penetrating trauma to the abdomen, pelvis, chest, neck, or head;
- Crush injury to the abdomen, chest, or head; or
- Fall from significant height.

- Neurologic considerations:
  - Glasgow Coma Scale score less than 10*;
  - Deteriorating mental status;
  - Skull fracture; or
  - Neurologic presentation suggestive of spinal cord injury.
- Thoracic considerations:
  - Major chest wall injury (e.g., flail chest);
  - Pneumothorax/hemothorax; or
  - Suspected cardiac injury.
- Abdominal/pelvic considerations:
  - Significant abdominal pain after blunt trauma;
  - Presence of a "seatbelt" sign or other abdominal wall contusion;
  - Obvious rib fracture below the nipple line; or
  - Major pelvic fracture (e.g., unstable pelvic ring disruption, open pelvic fracture, or pelvic fracture with hypotension).
- Orthopedic/extremity considerations:
  - Partial or total amputation of a limb (exclusive of digits);
  - Finger/thumb amputation when emergent surgical evaluation (i.e., for replantation consideration) is indicated, and rapid surface transport is not available;
  - Fracture or dislocation with vascular compromise;
  - Extremity ischemia;
  - Open long-bone fractures; or

- Two or more long-bone fractures.

- Major burns:
  - Greater than 20% body surface area;
  - Involvement of face, head, hands, feet, or genitalia;
  - Inhalational injury;
  - Electrical or chemical burns; or
  - Burns with associated injuries.
- Patients with near drowning injuries.

Non-trauma

The literature support for primary air ambulance transport of non-injured patients is limited to logistical considerations. It is conceivable that clinical indications for scene air response may be identified in the future. However, at this time prehospital providers should incorporate logistical considerations, clinical judgment, and medical oversight in determining whether primary air transport is appropriate for patients with non-trauma diagnoses.

Date	Summary of Changes
6/1/2026	• Transitioned Ambulance and Transport Services policy, 1370/20.000092 to Lifetime HealthCare Companies policy template • Annual review, removing emergent or urgent conditions from policy statements
3/1/2024	• Added additional information under paramedic intercept section in regard to non-volunteer BLS entities
6/1/2023	No Criteria changes:

	• Clarified air ambulance services for interfacility transports • Added verbiage in regards to reviewing medical necessity of air ambulance services • Under the Medicare section added the following Medicare Language: o air ambulance transportation for deceased members and o utilizing air ambulance vs ground ambulance
5/12/2023	• Removed expanded coverage added for the COVID-19 public health emergency
1/1/2023	• Added coverage criteria for air ambulance to the Child Health Plus section
9/1/2022	• Clarified paramedic intercept service
04/01/2020	• Updates related to COVID-19 pandemic

MEDICAL POLICY

Medical Policy Title	**Ambulance: Land/Ground**
Policy Number	**10.01.07**
Current Effective Date	**September 1, 2026**
Next Review Date	**March 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service.
(Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Emergency land/ground ambulance transportation is considered **medically appropriate** (when the New York State (NYS) mandate does not apply), when **ALL** of the following criteria are met:

- A. The services must be provided by an ambulance service that is issued a certificate under the NYS Public Health Law;
- B. The ambulance must have the necessary patient-care equipment and supplies;
- C. The individual's condition must be such that any other form of transportation would be medically contraindicated; **and**
- D. The individual is transported to the nearest hospital with the appropriate facilities for the treatment of the patient's illness or injury.

II. Non-emergent ambulance services for medical transport are considered **medically appropriate** when **ALL** of the following criteria are met:

- A. The services must be provided by an ambulance service that is issued a certificate under the NYS Public Health Law;
- B. The ambulance must have the necessary patient-care equipment and supplies;
- C. The individual's condition must be such that any other form of transportation would be medically contraindicated;
- D. The provider of the specialized service is the nearest facility with the required capabilities;

  and

- E. **One** of the following indications:
  1. From a non-participating hospital to a participating hospital;
  2. To a hospital that provides a higher level of care that was not available at the original hospital;
  3. When individual has been approved for interfacility transfer (CMP #11.01.18 Interfacility Transfer of a Registered Patient); **or**

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

4. From an acute care facility to a sub-acute setting.

III. Elective or convenience ambulance transportation (e.g., patient/patient's family desire, transportation from one facility to another facility within the same health care system for capacity management) is considered **not medically necessary**.

Administrative Policy

54 Ambulance-Transport Service

POLICY GUIDELINE(S)

I. When the NYS mandate does not apply to ambulance transportation, contractual distance restrictions may apply. Refer to the member's subscriber contract regarding specific limitations.

II. The non-emergent medical transport of a bed-confined patient, when specialized medical services during transport are not necessary, is considered to be a non-ambulance transportation and is **ineligible for coverage** as non-ambulance transportation, such as ambulette, van or taxicab is generally excluded by contract.

III. Transportation services utilizing vehicles that are not equipped and certified under the New York Public Health Law to provide emergency medical services (e.g., ambulette, van, or taxicab) are **ineligible for coverage** as they do not provide medical care or monitoring during transportation.

IV. Ambulance services for deceased members may be **eligible for coverage** if the patient is legally pronounced dead after the ambulance is called, but before pick-up or enroute to the hospital. These services are **ineligible for coverage** if the patient is pronounced dead before the ambulance is called.

V. Prior authorization for interfacility transfer is contract-dependent, and, where a member's subscriber contract so requires, authorization must be obtained prior to transfer of the patient. Some members' subscriber contracts exclude coverage for the transfer of its members between health care facilities.

VI. Accepting the transfer of a registered inpatient from another facility through the emergency department, when the patient is not in need of emergent services, does not negate the requirement for prior authorization of the transfer if the member contract requires prior authorization for inpatient admissions.

DESCRIPTION

Ambulance services involve the assessment and administration of care to the ill or injured individual by specially trained personnel and transportation of the individual in specially designed and equipped

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

vehicles within an appropriate, safe and monitored environment. The emergency medical personnel, ambulances, and equipment must follow New York State laws, codes, rules and regulations not addressed in this policy. Ambulance services are frequently the initial step in the chain of the delivery of medical care.

Ambulance and Medical Transport may involve:

- The emergency transportation of an individual to the nearest hospital with the appropriate facilities for the treatment of the individual's illness or injury; or
- The non-emergent medical transport of a registered hospital inpatient to another location to obtain medically necessary, specialized diagnostic, or therapeutic services.

Ambulance Services: Emergent, Urgent or Non-Emergent Reasons

I. An Emergency Condition is defined as services for a medical or behavioral condition that manifests itself by acute symptoms of sufficient severity, including severe pain, such that a prudent layperson, possessing an average knowledge of medicine and health, could reasonably expect the absence of immediate medical attention to result in:
   A. Placing the health of the person afflicted with such condition or, with respect to a pregnant woman, the health of the woman or her unborn child in serious jeopardy, or in the case of a behavioral condition, placing the health of such person or others in serious jeopardy;
   B. Serious impairment to such person's bodily function;
   C. Serious dysfunction of any body organ or part of such person; or
   D. Serious disfigurement of such person.

II. Urgent services are defined as services for a medical or behavioral condition that require immediate attention, although the condition may not be an emergency situation. An urgent care condition has the potential to become emergent in the absence of treatment.

III. Non-emergent services are defined as services for a medical or behavioral condition that are not considered to be of an emergent or urgent nature (e.g., elective surgery).

SUPPORTIVE LITERATURE

PROFESSIONAL GUIDELINE(S)

In an updated Joint Position Statement of the Recommended Essential Equipment for Basic Life Support and Advanced Life Support Ground Ambulances 2020 co-authored by National Association of Emergency Medical Services (EMS) Physicians (NAEMSP)/American Academy of Pediatrics (AAP)/ American College of Surgeons Committee on Trauma (ACSCOT)/EMS for Children Innovation and Improvement Center (EIIC)/Emergency Nurses Association (ENA)/National Association of State EMS Officials (NASEMSO) and endorsed by National Association of Emergency Medical Technicians (NAEMT), Lyng et al (2021b) stated that the delivery of high-quality and effective EMS care is

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

dependent on several factors, including but not limited to:

- Credentialed providers, who have demonstrated appropriate knowledge, ability, psychomotor skills, and critical thinking.
- Clinical protocols or guidelines supported by the best available scientific evidence.
- Equipment and supplies necessary to deliver appropriate care as indicated by clinical protocols/guidelines for patients of all ages.

The purpose of this statement is to review and revise the 2014 version of the joint position statement to include a review of equipment lists established by individual state/territory rules and statutes for all U.S. states and territories and to establish recommended equipment standards to build consistency across the EMS system of care and to facilitate advances in the delivery of quality and cost-effective EMS care. The statement also establishes that EMS agencies should include in their routine quality assurance practices efforts to assess that:

- Their EMS providers are outfitted with all necessary equipment for them to perform clinical care.
- All equipment and supplies undergo appropriate preventive maintenance and routine function checks.
- Malfunctioning or missing equipment issues are quickly addressed to preserve readiness to respond and provide patient care continuously.

The statement includes a list of required equipment for basic life support (BLS) Emergency Ground Ambulances and Advanced Life Support (ALS) Emergency Ground Ambulances, a list of optional equipment that should be used based on local needs and resources and a list of optional medications.

REGULATORY STATUS

The NYS Insurance Law mandates coverage for pre-hospital emergency services and land transportation provided by ambulance services certified under the NYS Public Health Law. The mandate requires coverage of pre-hospital emergency services and ground ambulance transport when a prudent layperson, possessing an average knowledge of medicine and health, could reasonably expect the absence of such transportation to result in:

- Placing the health of the person afflicted with such condition (or with respect to a pregnant woman, placing the health of the woman or her unborn child), in serious jeopardy, or in the case of a behavioral condition, placing the health of such person or others in serious jeopardy;
- Serious impairment to such person's bodily function;
- Serious dysfunction of any bodily organ or part of such person; or
- Serious disfigurement of such person.

The NYS mandate does not require coverage of air ambulance transportation and explicitly excludes ambulance transportation between hospitals or health care facilities.

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

The NYS mandate applies to all major medical or similar comprehensive-type contracts, including Health Maintenance Organization (HMO) contracts and Child Health Plus contracts.

PRODUCT DISCLAIMER

- Services are contract dependent; if a product does not cover a service, medical policy criteria do not apply.
- If a commercial product (including an Essential Plan or Child Health Plus product) covers a specific service, medical policy criteria apply to the benefit.
- If a Medicaid product covers a specific service, and there are no New York State Medicaid guidelines (eMedNY) criteria, medical policy criteria apply to the benefit.
- If a Medicare product covers a specific service, and there is no national or local Medicare coverage decision for the service, medical policy criteria apply to the benefit.
- CDPHP utilizes the New York State Medicaid Transportation Manual Policy Guidelines to determine ambulance coverage availability for Medicaid: https://www.emedny.org/ProviderManuals/Transportation/PDFS/Transportation_Manual_Policy_Section.pdf
- CDPHP utilizes the New York State Medicaid Transportation Manual Policy Guidelines to determine air ambulance coverage availability for Child Health Plus: https://www.emedny.org/ProviderManuals/Transportation/PDFS/Transportation_Manual_Policy_Section.pdf

POLICY HISTORY/REVISION	
Committee Approval Dates	
New: 10/92 **Revised**: 08/94, 04/97, 05/98, 04/99, 01/00, 10/02, 09/03, 04/04, 01/05, 10/05,07/08, 05/09, 5/10, 11/10, 05/11, 05/12, 07/12, 11/12, 05/13, 11/13, 01/14, 05/14, 05/15, 05/16, 05/18, 05/19, 04/20 (regulatory revision), 5/22, 1/23, 5/23, 11/23, 3/24, 5/26 **Reviewed**: 03/93, 08/95, 06/96, 03/01, 10/06, 09/06, 09/07, 05/17, 05/21, 5/24, 5/25	
Date	**Summary of Changes**
6/1/2026	• Transitioned Ambulance and Transport Services policy, 1370/20.000092 to Lifetime HealthCare Companies policy template. • Annual review. Removal of criteria for urgent ambulance transportation, and removal of criteria addressing cost effectiveness.
3/1/2024	• Added additional information under paramedic intercept section in regard to non-volunteer BLS entities.
6/1/2023	No Criteria changes: • Clarified air ambulance services for interfacility transports • Added verbiage in regards to reviewing medical necessity of air ambulance services • Under the Medicare section added the following Medicare Language: o Air ambulance transportation for deceased members and • Utilizing air ambulance vs ground ambulance
5/12/2023	• Removed expanded coverage added for the COVID-19 public health emergency
1/1/2023	• Added coverage criteria for air ambulance to the Child Health Plus section
9/1/2022	• Clarified paramedic intercept service
04/01/2020	• Updates related to COVID-19 pandemic

POLICY NAME: AMBULATORY ELECTROENCEPHALOGRAPHY (EEG)

POLICY EFFECTIVE DATE:	11/1/2024
Policy Control #:	1370/20.000519
Next Annual Review:	July 2027

DISCLAIMER

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgement when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

PROCEDURE CODES

Ambulatory Electroencephalography (EEG): 95700, 95705, 95706, 95707, 95708, 95709, 95710, 95711, 95712, 95713, 95714, 95715, 95716, 95717, 95718, 95719, 95720, 95721, 95722, 95723, 95724, 95725, 95726

Routine "Resting" Electroencephalography (EEG): 95812, 95813, 95816, 95819, 95822

DESCRIPTIONS

An electroencephalogram (EEG) is a diagnostic test that measures the electrical activity of the brain (brainwaves) using highly sensitive recording equipment attached to the scalp by fine electrodes. It is used to diagnose neurological conditions.

EEGs can be recorded by ambulatory cassette. Ambulatory cassette-recorded EEGs offer the ability to record the EEG on a long-term, outpatient basis. Electrodes for at least four (4) recording channels are placed on the patient. The cassette recorder is attached to the patient's waist or on a shoulder harness. Recorded electrical activity is analyzed by playback through an audio amplifier system and video monitors.

Ambulatory EEG monitoring may facilitate the differential diagnosis between seizures and syncopal attacks, sleep apnea, cardiac arrhythmias or hysterical episodes. The test may also

allow the investigator to identify the epileptic nature of some episodic periods of disturbed consciousness, mild confusion, or peculiar behavior, where resting EEG is not conclusive. It may also allow an estimate of seizure frequency, which may at times help to evaluate the effectiveness of a drug and determine its appropriate dosage.

POSITION STATEMENT

CDPHP considered ambulatory electroencephalography (EEG) medically necessary for the following indications:

- Inconclusive EEGs;
- Experiencing episodic events where epilepsy is suspected but the history, examination, and routine EEG do not resolve the diagnostic uncertainties;
- Patients with confirmed epilepsy who are experiencing suspected non-epileptic events or for classification of seizure type (only ictal recordings can reliably be used to classify seizure type (or types) which is important in selecting appropriate anti-epileptic drug therapy);
- Differentiating between neurological and cardiac related problems;
- Adjusting anti-epileptic medication levels;
- Localizing seizure focus for enhanced patient management;
- Identifying and medicating absence seizures;
- For suspected seizures of sleep disturbances;
- Seizures which are precipitated by naturally occurring cyclic events or environmental stimuli which are not reproducible in the hospital or clinic setting.

Ambulatory monitoring is not necessary to evaluate most seizures, which are usually readily diagnosed by routine EEG studies and history.

POLICY CONSIDERATIONS

Ambulatory electroencephalography (EEG) should always be preceded by a routine EEG. A routine EEG is described by Current Procedural Terminology (CPT) codes 95812, 95813, 95816, 95819, or 95822 and refers to a routine EEG recording of less than a 24-hour continuous duration.

A routine "resting" (EEG) (as described by CPT codes 95812, 95813, 95816, 95819 or 95822) must be performed prior to performing an ambulatory continuous EEG. A claim for the routine EEG must have been submitted to CDPHP with a date of service (DOS) within one year of the DOS of the ambulatory EEG.

Requirements for a routine "resting" EEG is waived for medically necessary continuous EEG performed in an intensive care unit (ICU).

POLICY NAME: AMBULATORY ELECTROENCEPHALOGRAPHY (EEG)

EXCLUSIONS

Ambulatory EEG is considered not medically necessary in circumstances including but not limited to the following:

- Study of neonates or unattended, non-cooperative patients;
- Localization of seizure focus/foci when the seizure symptoms and/or other EEG recordings indicate the presence of bilateral foci or rapid generalization.

PROCEDURE CODES

H0002, H0040, H2012, H2018, H2019, H2015, T1015, T2034

DESCRIPTION

Ambulatory mental health programs include the following:

- **Assertive Community Treatment (ACT) and Youth Assertive Community Treatment (Youth ACT)** – These comprehensive services are for individuals with serious mental illness whose needs have not been met by traditional service delivery approaches. ACT is an evidence-based practice that incorporates treatment, rehabilitation, case management, and support services delivered by a mobile, multi-disciplinary mental health team. ACT supports recipient recovery through an individualized approach that provides recipients with the tools to obtain and maintain housing, employment, relationships, and relief from symptoms and medication side effects. The nature and intensity of ACT services are developed through a person-centered service planning process and adjusted as needed in daily ACT team meetings.

- **Continuing Day Treatment (CDT)** – A program which provides seriously mentally ill adults with the skills and supports necessary to remain in the community or work toward a more

independent level of functioning. Participants often attend several days per week with visits lasting more than an hour.

- **Personalized Recovery Oriented Services (PROS) –** A comprehensive recovery oriented program for individuals with severe and persistent mental illness. Through a single plan of care, the program model integrates treatment, support, and rehabilitation in a manner that facilitates the individual's recovery. The PROS model is person-centered, strength-based, and comprised of a menu of group and individual services designed to assist a participant to overcome mental health barriers and achieve a desired life role.

- **Crisis Residential Services –** Crisis Residence Programs provide short-term interventions to individuals experiencing psychiatric crisis. These programs address the cause of the individual's psychiatric crisis and avert or delay the need for emergency department stabilization or acute psychiatric inpatient hospitalization. Programs provide supports to stabilize and transition individuals back to the community.

RELATED POLICIES/DOCUMENTS

None

POSITION STATEMENT

CDPHP does not provide coverage for Assertive Community Treatment (ACT), Continuing Day Treatment (CDT), or Personalized Recovery Oriented Services (PROS), except for Select Plan/HARP as described below.

POLICY CONSIDERATIONS

SELECT PLAN/HARP:

Benefits are provided for Assertive Community Treatment (ACT), Continuing Day Treatment (CDT), Personalized Recovery Oriented Services (PROS), and Crisis Residential Services when criteria outlined below is met.

POLICY NAME: AMBULATORY MENTAL HEALTH PROGRAMS

Assertive Community Treatment (ACT)

Eligibility Requirements
Enrollee is 18 years of age or older and meets either of the conditions outlined below.

Enrollee with serious functional impairments demonstrates at least one of the following conditions:

- Inability to consistently perform practical daily living tasks required for basic adult functioning in the community without significant support or assistance from others such as family, relatives or friends;
- Inability to be consistently employed at a self-sustaining level or inability to consistently carry out the homemaker role;
- Inability to maintain a safe living situation (e.g., repeat evictions or loss of housing).

OR

Enrollee with continuous high-service needs demonstrates one or more of the following conditions:

- Inability to participate or succeed in traditional, office-based services or case management
- High use of acute psychiatric hospitals (two hospitalizations within one year, or one hospitalization of 60 days or more within one year)
- High use of psychiatric emergency or crisis services
- Persistent severe major symptoms (e.g., affective, psychotic, suicidal or significant impulse control issues)
- Co-existing substance abuse disorder (duration greater than 6 months).
- Current high risk or recent history of criminal justice involvement
- Court ordered pursuant to MHL §9.60 to participate in Assisted Outpatient Treatment
- Inability to meet basic survival needs or homeless or at imminent risk of becoming homeless
- Residing in an inpatient bed or in a supervised community residence, but clinically assessed to be able to live in a more independent setting if intensive community services are provided
- Currently living independently but clinically assessed to be at immediate risk of requiring a more restrictive living situation (e.g., community residence or psychiatric hospital) without intensive community services

Admission/Continuing Stay
ACT serves persons who have a severe and persistent mental illness listed in the diagnostic nomenclature (current diagnosis per DSM IV) that seriously impairs their functioning in the community. Priority is given to people with schizophrenia, other psychotic disorders (e.g., schizo-affective disorder), bipolar disorder and/or major or chronic depression, because these illnesses more often cause long-term psychiatric disability. Priority is also given to individuals with continuous high-service needs that are not being met in more traditional service settings. Individuals with a primary diagnosis of a personality disorder(s), substance abuse disorder, or mental retardation are not appropriate for ACT.

Youth Assertive Community Treatment (Youth ACT)

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.
(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: AMBULATORY MENTAL HEALTH PROGRAMS

Youth Assertive Community Treatment (Youth ACT)
Youth Assertive Community Treatment (ACT) is a program designed to address the significant needs of children ages 10 up to 21, who are at risk of entering, or returning home from high intensity services, such as inpatient settings or residential services, through the use of a multi-disciplinary team. Children with significant psychiatric needs, who are at risk of institutional level of care, require intensive interventions in order to adequately support the child and family's complex needs, to avoid high end services or facilitate and support a successful transition back to community. Youth ACT serves as a critical component in the children's continuum of care.

Eligibility Requirements
- Enrollee is at least 10 at the time of enrollment and may be served up to the age of 21
- Enrollee must have a determination of Serious Emotional Disturbance (SED) defined as:
    - A child or adolescent having a designated mental illness diagnosis according to the most current Diagnostic and Statistical Manual of Mental Disorders AND has experienced functional limitations due to emotional disturbance over the past 12 months on a continuous or intermittent basis.
- Enrollee must have continuous high service needs that are not being met in more traditional service settings
- Enrollee's county of residence must be within the Youth ACT program's catchment area (i.e., county(ies) licensed to serve)

Referral, Admission, Continuing Stay, and Discharge
Admission to Youth ACT is managed through a local Children's Single Point of Access (C-SPOA). There are specific considerations for transition aged youth (TAY ages 18-21), as both Youth and Adult ACT teams can serve TAY individuals. For individuals on Assisted Outpatient Treatment (AOT), C-SPOA must make a referral to an Adult ACT team, as they have the expertise to serve these individuals. However, for those individuals not on an AOT, C-SPOA should take into consideration individual choice and the developmental and clinical needs of the individuals.

Enrollees/Families that meet any of the following criteria may be discharged:
- Enrollee and family no longer want to receive services through Youth ACT
- All parties involved concur that the enrollee has met the goals of his/her Individualized Service Plan and no longer requires Youth ACT services
- Enrollee no longer meets the definition of SED or has complex mental health needs requiring ACT level of care
- Enrollees who are hospitalized or locally incarcerated for three months or longer
- Enrollee has been admitted to another program (e.g., Community Residence, RTF)
- Enrollee turns 21
- Enrollee/family moves out of the geographic area served by the Youth ACT team in which they are enrolled. The Youth ACT team is responsible for transfer of mental health service to an appropriate provider and must maintain contact with the child/family until the provider and child/family are engaged in this new service arrangement.

Continuing Day Treatment (CDT)

Eligibility Requirements
- Enrollee is 18 years of age or older; **and**
- Enrollee has a designated mental illness diagnosis; **and**

- Enrollee has a function disability due to the severity and duration of mental illness; **and**
- Services are recommended by a licensed practitioner of healing arts

Admission
Enrollee must (all of the following):
- Have three or more areas of significant impairment in functioning
- Be experiencing symptoms impairing thought, mood, behavior or perception that interfere with the ability to function with a lesser level of service.
- Have cognitive capacity to engage in and benefit from this level of treatment
- Reasonably be expected to benefit in improved functioning at work, school, or social relationships
- Need a highly structured, focused treatment approach to accomplish improvement and to avoid relapse requiring higher level of treatment

Continuing Stay
For enrollee to continue treatment, the following criteria must be met (all of the following):
- Condition continues to meet admission criteria
- Treatment plan contains specific goals and documented measurable progress toward goals
- An active discharge plan is in place
- Attempts to coordination care and transition to other services are documented, as clinically indicated
- Interventions provided and enrollee's response documented in the enrollee's daily record

Personalized Recovery Oriented Services (PROS)

Eligibility Requirements
- Enrollee is 18 years of age or older; **and**
- Enrollee has a designated mental illness diagnosis; **and**
- Enrollee has a function disability due to the severity and duration of mental illness; **and**
- Services are recommended by a licensed practitioner of healing arts

Pre-Admission
The provider does not need to submit an initial service recommendation (ISR) for the pre-admission phase.

Admission
PROS provider will have 60 days from admission to develop an *Individualized Recovery Plan* (IRP). Services identified in the IRP may include:
- Intensive Rehabilitation (IR);
- Ongoing Rehabilitation and Supports (ORS);
- Clinical Treatment (CT);
- Community Rehabilitation and Support (CRS)

Active Rehabilitation
Once the IRP is completed, the enrollee is now in active rehabilitation. The IRP is reviewed and updated, at a minimum, every six months.
- For enrollees receiving Intensive Rehabilitation or Ongoing Rehabilitation and Supports, these

services identified in the IRP are to be assessed, at a minimum, every three months for continued need.
- Community Rehabilitation and Support (CRS) and clinic treatment (CT) services are reviewed, at a minimum, every six months.

Continued coverage is available when documentation confirms one of the following:
- Enrollee has an active recovery goal and shows progress toward achieving it; **or**
- Enrollee has met and is sustaining a recovery goal, but would like to pursue a new goal; **or**
- Enrollee requires a PROS level of care in order to maintain psychiatric stability and there is not a less restrictive level if care that is appropriate; **or**
- Without PROS services, the enrollee would require a higher level of care

Crisis Residential Services

There are two Crisis Residential Service Programs available to individuals aged 18 and older.

Residential Crisis Support Programs

Voluntary residential program for individuals experiencing symptoms of mental illness and/or challenges in daily life that create risk for an escalation of symptoms that cannot be managed in the individual's home and community environment without onsite supports. Individuals receive Residential Crisis Support Program services for up to 28 days.

Mental health diagnosis is not required to receive Residential Crisis Support Program services.

Service Components:
- Service Planning
  - Engagement with identified supports
  - Safety planning
  - Integration of direct care and support services
- Care Coordination
  - Case management activities that emphasize discharge planning
  - Collaboration and linkages with service options in the community that provide continuation of ongoing treatment and rehabilitation
- Peer Support
- Assistance in personal care and activities of daily living
- Medication management, monitoring, and training
- Crisis Respite
- For individuals 18-20:
  - Mental Health Assessment
  - Individual and Family Counseling
  - Family Support

Intensive Crisis Residence Programs

Voluntary residential treatment program for individuals experiencing a psychiatric crisis, including acute escalation of mental health symptoms. The program is short-term (up to 28 days). Individuals in need of this program are at imminent risk for loss of functional abilities and may raise safety concerns for themselves and others without this level of care. The immediate goal of this program is to provide treatment and supports to help the individual stabilize and return to previous levels of functioning.

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.
(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: AMBULATORY MENTAL HEALTH PROGRAMS

Intensive Crisis Residence Programs can also be used as an inpatient hospitalization step-down service after discharge.

Mental health diagnosis is required to receive Intensive Crisis Residence Program services.

Service Components:

- Comprehensive Assessment
- Service Planning
  - Engagement with identified supports
  - Safety planning
  - Integration of direct care and support services
- Care Coordination
  - Case management activities that emphasize discharge planning
  - Collaboration and linkages with service options in the community that provide continuation of ongoing treatment and rehabilitation
- Individual and family counseling
  - Medication therapy
  - Individual and group counseling
  - Engagement and support to address co-occurring disorders
- Assistance in personal care and activities of daily living
- Medication management, monitoring, and training
- Crisis respite

EXCLUSIONS

Individuals with a primary diagnosis of a personality disorder(s); substance abuse disorder or mental retardation are not appropriate for ACT.

Individuals with a primary diagnosis of a personality disorder(s), or solely a substance use disorder without having co-occurring and significant mental health needs and diagnosis, are not appropriate for Youth ACT.

Children with Developmental Disabilities: Children with an IQ of 51 and above may be eligible for Youth ACT. Youth ACT is equipped to serve children whose IQ is 80 and above. For children whose IQ is 51-69, determinations will be made on a case by case basis. Children whose IQ is below 51 are not appropriate for Youth ACT.

CDPHP PRODUCT VARIATIONS

CHILD HEALTH PLUS:	Child Health Plus provides coverage for Assertive Community Treatment (ACT), Youth ACT, and select Crisis Intervention services under Children and Family Treatment and Support Services (CFTSS). See Ambulatory Mental Health Programs for Children Policy for additional information. Child Health Plus does not provide coverage for Continuing Day

PROCEDURE CODES

65778	Placement of amniotic membrane on the ocular surface; without sutures
65779	Single layer, sutured
65780	Ocular surface reconstruction; amniotic membrane transplantation, multiple layers
65781	Limbal stem cell allograft (e.g., cadaveric or living donor)
65782	Limbal conjunctival autograft (includes obtaining graft)
V2790	Amniotic membrane for surgical reconstruction, per procedure

DESCRIPTIONS

Human amniotic membrane is a unique collagenous membrane derived from the innermost submucosa of the placenta. It consists of a collagen-rich thick basement membrane and an avascular stroma. Amniotic tissue has been used in a variety of surgical procedures to cover a defect on the surface of the eye and facilitate wound healing as well as decreasing inflammation. Some defects are created by the surgical excision of lesions or necrotic tissue while others result from injury, infection, or degeneration. The usefulness of amniotic membrane has been attributed to its anti-inflammatory, anti-fibrotic, anti-vascularization, and anti-scarring effects, and also to its ability to enhance epithelial healing.

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: AMNIOTIC MEMBRANE PLACEMENT FOR TREATMENT OF OCULAR SURFACE DISORDERS

Amnion can be prepared for implantation several ways. Heat or air-dried amniotic membrane loses some of its biologic properties and is not ideal for ocular surface rehabilitation. The tissue can be lyophilized (freeze dried), which induces minimal change in its properties. Amnion can be preserved in cold glycerol and cryopreserved and stored frozen at -80 degrees. The cryopreservation method allows for greater retention of the membrane's structural, physiological, and biochemical properties responsible for its dramatic healing and easier handling intraoperatively.

RELATED POLICIES/DOCUMENTS

Payment Policies:

Adjunct and Non-Standard Technologies, 1550/20.000187

POSITION STATEMENT

CDPHP considers preserved human amniotic membrane transplantation medically necessary for the treatment of ocular surface defects including, but not limited to:

- There may be circumstances where there is a severe condition requiring acute treatment with amniotic membrane such as chemical, thermal or radiation injuries, or Stevens Johnson Syndrome, or limbal stem cell failure.
- Band keratopathy after treatment with other therapy such as surgery, topical medications, bandage contact lens, or patching.
- Bullous keratopathy associated with an epithelial defect.
- Scleral melting.
- Corneal ulcer following initiation of anti-infective therapy and demonstration of clinical response for the purpose of healing the persistent epithelial defect.
- Chemical burns of the ocular surface.
- Conjunctival defects after treatment with other therapy such as surgery or topical medications.
- Corneal melting.
- Limbal Stem Cell Deficiency.
- Pterygium
- Recurrent corneal erosions after treatment failure with other therapy such as bandage contact lens, patching, and topical medications.

In addition to the criteria above, the following ICD-10 codes support medical necessity for amniotic membrane transplantation:

POLICY NAME: AMNIOTIC MEMBRANE PLACEMENT FOR TREATMENT OF OCULAR SURFACE DISORDERS

Code	Description
H04.131 - H04.139	Lacrimal cyst, right lacrimal gland - Lacrimal cyst, unspecified lacrimal gland
H11.001 – H11.069	Pterygium of eye
H15.89 - H15.9*	Other disorders of sclera - Unspecified disorder of sclera
H16.001 - H16.079*	Unspecified corneal ulcer, right eye - Perforated corneal ulcer, unspecified eye
H16.121 - H16.129	Filamentary keratitis, right eye - Filamentary keratitis, unspecified eye
H16.231 - H16.239	Neurotrophic keratoconjunctivitis, right eye - Neurotrophic keratoconjunctivitis, unspecified eye
H18.10 - H18.13	Bullous keratopathy, unspecified eye - Bullous keratopathy, bilateral
H18.421 - H18.429	Band keratopathy, right eye - Band keratopathy, unspecified eye
H18.831 - H18.839	Recurrent erosion of cornea, right eye - Recurrent erosion of cornea, unspecified eye
H18.891 - H18.899	Other specified disorders of cornea, right eye - Other specified disorders of cornea, unspecified eye
L51.0	Nonbullous erythema multiforme
L51.1	Stevens-Johnson syndrome
L51.3	Stevens-Johnson syndrome-toxic epidermal necrolysis overlap syndrome
L51.9	Erythema multiforme, unspecified
T26.00XA - T26.92XS	Burn of unspecified eyelid and periocular area, initial encounter - Corrosion of left eye and adnexa, part unspecified, sequela

Amniotic membrane transplantation is considered experimental and investigational for all other indications.

* The unspecified diagnosis codes in these ranges (H15.89-H15.9 and H16.001-H16.079) should only be used if no other more specific diagnosis code exists that describes the condition being treated. If one of these diagnosis needs to be used, the supporting documentation must clearly describe in detail the indication the membrane is being used to treat.

POLICY CONSIDERATIONS

Amniotic membrane must be cleared by, or registered with, the U.S. Food and Drug Administration (FDA) for application of the eye.

- The U.S. Food and Drug Administration regulates human cells and tissues intended for implantation, transplantation, or infusion through the Center for Biologics Evaluation and Research, under Code of Federal Regulation, title 21, parts 1270 and 1271.

HCPCS code V2790 (amniotic membrane for surgical reconstruction, per procedure) is included in the allowance for CPT procedure code 65778. Therefore, V2790 should not be billed

separately when this code is billed.

EXCLUSIONS

Application for dry eye syndrome is non-covered, given no demonstrated impact on long term outcome.

PROCEDURE CODES

97151, 97152, 97153, 97154, 97155, 97156, 97157, 97158

DESCRIPTION

According to the American Psychiatric Association Diagnostic and Statistical Manual of Mental Disorders, 5th Edition (DSM 5), the essential features of Autism Spectrum Disorder (ASD) are persistent impairment in reciprocal social communication and social interaction (Criterion A), and restricted, repetitive patterns of behavior, interests or activities (Criteria B). These symptoms are present from early childhood and limit or impair everyday functioning (Criteria C and D). Manifestations of the disorder also vary greatly depending on the severity of the autistic condition, developmental level, and chronological age. Autism spectrum disorder encompasses disorders previously referred to as early infantile autism, childhood autism, Kanner's autism, high-functioning autism, atypical autism, pervasive developmental disorder not otherwise specified, childhood disintegrative disorder, and Asperger's disorder.

The Agency for Healthcare Research and Quality (AHRQ) Comparative Effectiveness Review (2011) defines applied behavior analysis (ABA) as an umbrella term describing principles and techniques used in the assessment, treatment, and prevention of challenging behaviors and the promotion of new desired behaviors. The goal of ABA is to teach new skills, promote

generalization of these skills, and reduce challenging behaviors with systematic reinforcement.

As a treatment modality for ASD, ABA involves a systematic analysis of behavior, utilizing careful observation to identify those behaviors that are triggered by environmental factors and are interfering with socialization and learning. An individualized treatment plan is designed using positive reinforcement and rewards designed to change behavior. ABA focuses on explaining behaviors in terms of environmental events that can be manipulated and modified rather than biological forces that are beyond the individual's control.
ABA may also be referred to as, Lovaas therapy or early intensive behavioral intervention (EIBI).

RELATED POLICIES/DOCUMENTS

N/A

POSITION STATEMENT

In accordance with New York State law, CDPHP administers benefits for ABA therapy when necessary to develop, maintain, or restore, to the maximum extent practicable, the functioning of an individual when all of the following criteria are met:

1.
2. Benefits for Applied Behavior Analysis (ABA) are available to individuals of any age and for any diagnosis where Applied Behavior Analysis (ABA) is an appropriate treatment modality.
3. Interventions are consistent with ABA techniques and are provided or supervised by a board certified behavior analyst, or other qualified health professional.
4. There is documentation of severe behavior that:
   - Presents a health or safety risk to self or others; or
   - Significantly interferes with home or community activities.
5. Less intensive behavior treatment has been unsuccessful in managing or treating the behaviors.
6. There has been established a reasonable expectation on the part of the therapist that the ABA treatment will significantly improve the behaviors.
7. Documentation supports the position that therapy will achieve functional gains beyond those expected as a result of growth and maturation.
8. The treatment plan is built on individual and measurable goals and interventions that emphasize generalization of skills learned.
9. Caregiver training and support is a part of the treatment plan.
10. Treatment intensity (i.e., number of hours per day or per week) and duration (i.e., length of service intervention) is individualized and designed to meet needs of the patient and adjusted as clinically appropriate.
11. Treatment plan addresses comorbid medical and psychiatric disorders, and includes

coordination of care with other providers and community based-resources, as appropriate.

POLICY CONSIDERATIONS

Care rendered by a non-network applied behavior analyst will be subject to the Plan's out-of-network benefit.

*** APPLICABLE CODES:**

ICD-10 Description	ICD-10 codes
Autistic disorder	F84.0
Rett's syndrome	F84.2
Other childhood disintegrative disorder	F84.3
Asperger's syndrome	F84.5
Other pervasive developmental disorders	F84.8
Pervasive developmental disorder, unspecified	F84.9

EXCLUSIONS

ABA services are no longer considered medically necessary when any of the following occur:

- The individual has achieved adequate stabilization and less intensive modes of treatment are appropriate and indicated.
- There has been no meaningful improvement in the patient's behavior after a significant period of treatment.
- The treatment is making the behaviors worse.
- The treatment has demonstrated the inability to maintain long-term gains.
- Medical conditions or impairments are present that would prevent beneficial utilization of ABA services.

ABA treatment will **not** be certified for the following services:

- Vocational rehabilitation
- Supportive respite care
- Recreational therapy
- Orientation and mobility
- Equine therapy
- Hippotherapy
- Dolphin therapy

ABA therapy that duplicates services already being provided by a federal or state agency (i.e., Early Intervention Program) or by a school district (under an Individualized Educational Program) that are sufficient in meeting the needs of an individual.

POLICY HISTORY

This section is intended to provide only highlights of the policy changes. The policy should always be reviewed in its entirety to ensure a comprehensive understanding of coverage.

Effective Date	Update
9/1/24	Changed policy name to "Applied Behavioral Analysis" (removed "For Autism Spectrum Disorders) as ABA is covered for appropriate DSM-V diagnoses. Added ABA allowed for any age and for any diagnosis where Applied Behavior Analysis (ABA) is an appropriate treatment modality, for all LOB
6/1/23	Medicaid allowed for coverage of ABA for all ages and appropriate diagnoses.
4/1/23	Medicaid added coverage for 97154 & 97157. Medicaid now covers all codes listed in this policy.
1/1/2023	Added coverage for Medicaid
10/1/2021	Removed limits for ABA testing Added coverage for Medicaid per NYS update effective 10/1/21 - ONLY Codes 97151, 97152, 97153, and 97155 Added per 8/10/2021 MMC Plan Update: "Additional providers have been added to the list of providers that may diagnose/refer for ABA services. The providers added are pediatric nurse practitioners and physician assistants."
1/1/2020	Updated maximum hour limits for ABA Services in Policy Considerations section.

MEDICAL POLICY

Medical Policy Title	**Aqueous Drainage Devices (Stents and Shunts) for Glaucoma**
Policy Number	**9.01.18**
Current Effective Date	**August 1, 2026**
Next Review Date	**January 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Insertion of an aqueous drainage device that has been approved by the United States Food and Drug Administration (FDA) is considered **medically appropriate** in patients with glaucoma for **EITHER** of the following indications:

   A. Medical therapy has failed to adequately control the intraocular pressure (IOP);

   B. Oral or topical medications are not tolerated by the patient (e.g., oral medications cause significant gastrointestinal (GI) effects or topical medications cause contact sensitivity or systemic effects).

II. Implantation of one (1) or two (2) FDA-approved micro-stents (e.g., iStent or iStent Inject) in conjunction with cataract surgery is considered **medically appropriate** when the **ALL** of the following criteria are met:

   A. Diagnosed with mild-to-moderate open-angle glaucoma (OAG);

   B. Currently being treated with ocular hypotensive medication(s).

III. The use of aqueous drainage devices inserted into the suprachoroidal space or supraciliary space in patients with glaucoma are considered **investigational**.

IV. All other uses of aqueous drainage devices, including but not limited to use in patients with glaucoma when IOP is adequately controlled by medications, are considered **investigational**.

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

DESCRIPTION

Glaucoma is a chronic disorder involving increased pressure in the eye due to fluid build-up. There are several forms of glaucoma, with OAG being the most common. The increased pressure associated with OAG can lead to optic neuropathies characterized by visual field loss and structural damage to the optic nerve fiber. If left untreated, glaucoma can result in partial or complete visual impairment. Currently, IOP is the only treatable risk factor for glaucoma, and lowering IOP has proven beneficial in reducing the progression of loss of vision.

In most cases, topical or oral medication is the first treatment of choice. Glaucoma surgery (e.g., trabeculectomy) is intended to reduce IOP when the target IOP cannot be reached with medications. Due to complications with established surgical approaches such as trabeculectomy, a variety of devices, including aqueous shunts, are being evaluated as alternative surgical treatments for patients with inadequately controlled glaucoma. Microstents are also being evaluated in patients with mild to moderate OAG that is currently treated with ocular hypotensive medication.

Aqueous shunts, also known as aqueous drainage devices, glaucoma drainage devices, setons, tube implants, and tube shunts, are implanted into the eye to create an alternate path for aqueous humor to drain from the anterior or posterior chamber of the eye to a space between the conjunctiva and the sclera where it is absorbed into the blood, thereby lowering the IOP. These devices differ depending on explant surface areas, shape, plate thickness, presence or absence of a valve, and details of surgical installation. Generally, the risk of hypotony (low pressure) is reduced with aqueous shunts, in comparison with trabeculectomy, but IOP outcomes are higher than after standard guarded filtration surgery. Complications of anterior chamber shunts include corneal endothelial failure and erosion of the overlying conjunctiva. The risk of post-operative infection is lower than after trabeculectomy, and failure rates are similar, with about 10% of devices failing each year. The primary indication for aqueous shunts is that prior medical or surgical therapy has failed, although some ophthalmologists have advocated their use as a primary surgical intervention, particularly for selected conditions such as congenital glaucoma, trauma, chemical burn, or pemphigoid.

Other aqueous stents (e.g., microstents) are being developed as minimally penetrating methods to drain aqueous humor from the anterior chamber into Schlemm's canal or the suprachoroidal space. These include the iStent (Glaukos), which is a 1-mm long stent inserted into the end of Schlemm's canal by an internal approach through the cornea and anterior chamber, and the third generation iStent supra, which is designed for ab interno implantation into the suprachoroidal space. An advantage of ab interno shunts is that they may be inserted into the same incision while cataract surgery is being performed. In addition, most devices do not preclude subsequent trabeculectomy if needed. It may also be possible to insert more than one shunt to achieve the desired IOP.

SUPPORTIVE LITERATURE

Sheybani et al (2023) conducted a prospective, randomized, multicenter, noninferiority trial comparing gel stent (XEN45) versus trabeculectomy in patients (N=139) with open angle glaucoma and IOP of 15 to 44 mm Hg while receiving topical IOP medication. Patients were randomized 2:1 to gel stent implantation or trabeculectomy. At 12 months XEN45 was noninferior to trabeculectomy in

terms of surgical success which was defined as at least a 20% reduction in IOP without a medication increase, clinical hypotony, vision loss, or secondary surgical intervention (between group difference, -6.1%; 95% CI, -22.9% to 10.8%). XEN45 resulted in fewer in-office postoperative interventions and faster visual recovery, and greater six-month improvements in visual function problems than trabeculectomy.

Randomized, controlled trials (RCTs) have shown that the use of large, externally placed shunts with extraocular reservoirs results in success rates as good as standard filtering surgery (trabeculectomy). Shunts have a different side effect profile and avoid some of the most problematic complications of trabeculectomy.

Gedde and colleagues (2012) reported five-year follow-up from an open-label, multicenter, randomized tube versus trabeculectomy (TVT) study. The study included 212 eyes of 212 patients (aged 18 to 85 years) who had previous trabeculectomy and/or cataract extraction with intraocular lens implantation, uncontrolled glaucoma with IOP of 18 mm Hg or greater, as well as 40 mm Hg or lower on maximal-tolerated medical therapy. Patients were assigned either a tube shunt (Baervelt implant, n=107) or trabeculectomy with mitomycin C (n=105). Excluding patients who had died, the study had 82% follow-up at five years, with a similar proportion of patients in the tube and trabeculectomy groups. At five years, neither IOP (14.3 mm Hg in the tube group and 13.6 mm Hg in the trabeculectomy group) nor number of glaucoma medications (1.4 in the tube group and 1.2 in the trabeculectomy group) were significantly different with intent-to-treat analysis. The cumulative probability of failure over the five years was lower in the tube group than the trabeculectomy group (29.8% versus 46.9%), and the rate of reoperation was lower (9% versus 29%). The rate of loss of two or more lines of visual acuity was similar in the two groups (46% in the tube group and 43% in the trabeculectomy group).

Implantation of the Ex-PRESS mini shunt under a scleral flap was compared with standard trabeculectomy in a randomized study of 78 patients (80 eyes) with a diagnosis of OAG that could not be controlled with maximal-tolerated medical therapy (de Jong 2009). The two groups were similar after randomization, with the exception of difference in the mean age (62 years for the Ex-PRESS group and 69 years for the trabeculectomy group). At an average 12 months' follow-up, mean IOP had improved from 23 to 12 mm Hg in the Ex-PRESS group and from 22 to 14 mm Hg in the trabeculectomy group. Both groups of patients used fewer anti-glaucoma medications post-operatively than before the procedure (from 2.8 at baseline to 0.3 in the Ex-PRESS group and from 3.0 at baseline to 0.6 in the trabeculectomy group). Twelve-month Kaplan-Meier success rates (defined as an IOP of > 4 mm Hg and $\leq$ 18 mm Hg without use of anti-glaucoma medications) were 82 percent for the Ex-PRESS shunt and 48 percent for trabeculectomy. There was a similar level of postoperative complications in the two groups.

A 2017 Cochrane Systematic Review (Tseng 2017) found that there was insufficient information to conclude whether aqueous shunts or trabeculectomy yielded superior results, with heterogenous methodology and data quality across studies. Therefore, the selection of aqueous shunts or trabeculectomy should be left to the discretion of the treating ophthalmologist, in consultation with the individual patient. The term minimally invasive glaucoma surgery, or MIGS, refers to a group of surgical procedures that are performed using an ab interno approach and involve minimal trauma to

ocular tissues. Limited long-term data is currently available for MIGS, given its relatively recent introduction. Modest IOP reduction has been reported following MIGS, and postoperative pressures are typically in the middle to upper teens. Although less effective in lowering IOP than trabeculectomy and aqueous shunt surgery, MIGS appears to have a more favorable safety profile in the short term. Currently available MIGS includes procedures targeting the trabecular meshwork/Schlemm's canal and the subconjunctival space. They are commonly combined with phacoemulsification; some are only FDA approved to be performed concurrently with phacoemulsification.

Use of microstents has been studied in patients with both cataracts and less advanced glaucoma, where the IOP is at least partially controlled with medication. Results from these studies indicate that IOP may be lowered below baseline with decreased need for medication, although the benefit appears to diminish after the first year. Samuelson et al (2011) conducted a multi-center RCT to assess the safety and efficacy of cataract surgery with iStent (n=111) compared to cataract surgery without iStent (control group) (n=123). Patients had OAG and a plan to undergo phacoemulsification for cataracts. Follow-ups occurred for up to 12 months. The primary outcome measure was IOP less than or equal to 21 mmHg without ocular hypotensive medication, and the secondary measure was greater than or equal to 20 percent reduction in IOP from baseline without medication. Additional efficacy measures included medication use and visual acuity. Compared to the control group, significantly more patients in the treatment group achieved primary and secondary outcomes ($p<0.001$, $p=003$, respectively). At the 12-month follow-up, 70 percent of the treatment group versus 50 percent of the control group had achieved both the primary and secondary outcomes. There was a significant delay in the introduction of medication in the treatment group versus the control group ($p<0.001$), and significantly more patients in the control group required medication at 12 months ($p=0.001$). The overall adverse events were similar in both groups. Both groups improved in vision, with no significant differences between the groups.

Craven and colleagues (2012) reported two-year follow-up of the above-noted iStent study. There were 199 of the original 239 patients (83%) remaining in the study. The primary endpoint, IOP of 21 mm Hg or less without use of medication, was reached by 61 percent of patients in the treatment group, compared to 50 percent of patients in the control group ($p=0.036$). The secondary outcomes of IOP reduction of 20 percent or more without medication (53% versus 44%) and mean number of medications used (0.3 versus 0.5) were no longer significantly different between the groups at two years. As noted by the FDA, this study was conducted in a restricted population of patients who had an unmedicated IOP of 22 mm Hg or higher and 36 mm Hg or lower. The results of this study indicate that treatment of this specific population with a microstent is likely to improve outcomes at one year, compared to cataract surgery alone.

Chen and colleagues (2020) performed a meta-analysis to evaluate the effectiveness of iStent as a standalone operation in patients with OAG. Prospective and retrospective clinical studies written in English that investigated the effect of iStent in at least five eyes were included. A total of 17 studies involving 978 eyes with 599 eyes implanted with the first-generation iStent and 379 eyes with the second-generation iStent were analyzed. Follow-up duration varied among studies with the longest follow-up extending 42 months. The number of iStents varied from one to three stents per eye with

75.5% of eyes implanted with two stents. All studies reported a reduction in IOP after iStent implantation. Pooled result demonstrated a significant standardized mean difference (SMD) of −2.64. The majority of studies also reported a reduction in the number of medications at the end point compared to baseline with an overall SMD of -1.71. The authors determined moderate heterogeneity in studies evaluating the SMDs of IOP, as well as the number of medications. Most of the studies had a complication rate of less than 20%. Subgroup analyses revealed the higher number of iStents resulted in a greater IOP reduction. The authors concluded iStent can reduce the IOP and the number of medications in patients with OAG as a standalone procedure. Limitations include potential publication bias with several industry sponsored studies and substantial heterogeneity among studies. Included studies tended to have small sample sizes and lacked a control group.

Fan Gaskin et al (2024) reported on a prospective, randomized, assessor-masked controlled trial with 87 patients (n=101 eyes) that compared the effectiveness of cataract surgery plus iStent Inject implantation versus cataract surgery alone in patients with mild-to-moderate glaucoma. At the 24-month follow-up, the iStent Inject group used significantly fewer medications compared to the cataract surgery alone group (mean, 0.7 vs. 1.5; p=.008) and had a higher proportion of patients taking no glaucoma medications (57% vs. 36%). At 4 weeks post-surgery, a lower IOP was observed in the iStent group (mean difference, -2.8 mmHg [95% CI, -4.7 to -1]) but there was no difference in subsequent follow-up assessments. Both groups showed improvement in patient-reported outcomes from baseline levels (Ocular Surface Disease Index score and Glaucoma Activity Limitation Questionnaire), with no significant differences between groups. The safety profiles were similar between the two groups. The authors concluded this study showed combined cataract surgery with iStent Inject achieved a clinically- and statistically-significantly greater reduction in ocular hypotensive medication usage at 24-months compared to cataract surgery alone, with no significant difference in IOP.

Hengerer et al (2024) conducted a prospective, non-randomized, unmasked, longitudinal study (n=125) which evaluated 7-year effectiveness and safety of second-generation trabecular micro-bypass implantation (iStent inject) either in combination with cataract surgery or as a standalone procedure (combined or standalone subgroups, respectively) in eyes with open-angle glaucoma. Patients had considerable preoperative disease burden, with mean intraocular pressure (IOP) of 23.5 mmHg, 84.8% of eyes on C 2 medications, and 38.4% of eyes with prior glaucoma surgery. IOP, medications, adverse events, and secondary surgeries were assessed through 7 years in the overall cohort and in combined (n = 81) and standalone (n = 44) subgroups. Over 7-year follow-up, mean IOP decreased by 36.2–40.0% in Overall eyes, 34.1–38.9% in Combined eyes, and 39.5–43.5% in Standalone eyes. Mean medications decreased by 59.3–71.3% in Overall eyes, 57.9–69.0% in Combined eyes, and 62.1–76.2% in Standalone eyes. At last follow-up versus preoperative, 100% of eyes in all groups had the same or lower IOP and 100% had the same or lower medication regimen. The authors concluded this study showed iStent inject implantation with or without phacoemulsification produced significant and durable 7-year reductions in IOP (34–44% reduction) and medications (58–76% reduction) while preventing filtering surgery with favorable safety outcomes.

Sarkisian et al (2023) published the results of an open-label, single-arm, pivotal study evaluating

iStent infinite in patients with OAG uncontrolled by prior surgical or medical therapy. A total of 72 patients were enrolled from 15 sites in this trial. All patients were implanted with the iStent infinite System and received 3 stents. The majority of patients had failed prior surgery (n=61), and the remainder were uncontrolled on medical therapy (n=11). At 12 months the proportion of patients achieving at least 20% reduction in IOP and receiving the same or fewer medications was 76.1% (95% CI, 66.2% to 86.1%). The mean reduction in IOP at12 months was 5.9 mm Hg (standard error, 0.6; 95% CI, 4.8 to 7.1). No serious device-related adverse events were reported; however, blepharitis (4.2%), IOP increase requiring surgical intervention (4.2%), loss of best spectacle corrected visual acuity of 2 lines or more (8.3%), ocular surface disease (9.7%), and visual field loss of at least 2.5 dB were commonly reported adverse events. Stent migration and stent obstruction were each reported in 2 patients. Although this trial indicates positive outcomes with iStent infinite, the small sample size and lack of a control group are significant limitations.

Shultz et al (2025) conducted a manufacturer sponsored, multicenter study to evaluate the effectiveness and safety of iStent infinite, a trabecular microbypass implant, combined with phacoemulsification (n=233 eyes). In all eyes with 12-month follow-up data (n = 96, consistent cohort), the mean IOP reduced from 17.2 ± 4.2 mmHg preoperatively to 13.8 ± 3.0 mmHg at Month 12 ($p = 0.001$), while the mean number of medications reduced from 1.24 ± 0.91 preoperatively to 0.61 ± 0.96 at month 12 ($p = 0.001$). The proportions of eyes achieving IOP ≤ 18/15/12 mmHg increased from 63.5%, 34.4%, and 14.6% preoperatively to 92.7%, 71.9%, and 37.5%, respectively at month 12, (all $p = 0.001$). The proportions of eyes off medication increased from 16.7% preoperatively to 62.5% at Month 12 ($p = 0.001$). A noted limitation of the data analysis is that cases were completed in combination with cataract surgery, so it was not possible to delineate the potentially IOP-lowering effect of lens extraction from that of iStent infinite implantation. The authors conclude that this manufacturer sponsored study demonstrates reductions in IOP and the number of topical glaucoma medications required following iStent infinite trabecular micro-bypass and phacoemulsification.

PROFESSIONAL GUIDELINE(S)

The American Academy of Ophthalmology (AAO) published a technology assessment on commercially available aqueous shunts, including the Ahmed, Baerveldt, Krupin, and Molteno devices (Minckler 2008). This review indicated that the IOP will generally settle at higher levels (approximately 18 mm Hg) with aqueous shunts than after standard trabeculectomy (14-16 mm Hg) or after trabeculectomy with antifibrotic agents 5-fluorouacil or mitomycin C (8-10 mm Hg). In one study, IOPs with the Baerveldt shunt and adjunct medications were found to be equivalent to trabeculectomy with mitomycin C (13 mm Hg). Five-year success rates for the two procedures were found to be similar (50%). The assessment concluded that, based on level 1 evidence, aqueous shunts were comparable to trabeculectomy for IOP control and duration of benefit. The risk of postoperative infection was lower with aqueous shunts than after trabeculectomy. Complications of aqueous shunts were noted to include immediate hypotony after surgery; excessive capsule fibrosis and clinical failure; erosion of the tube or plate edge; strabismus; and, very rarely, infection. The most problematic long-term consequence of anterior chamber tube placement was described as accelerated damage to the

corneal endothelium over time.

AAO published a technology assessment on aqueous shunts with extraocular reservoir for open-angle adult glaucoma (Chopra 2024). They concluded that the implantation of aqueous shunts with extraocular reservoir, including valved or nonvalved devices, has been shown to be an effective strategy to lower IOP. Strong level I evidence supports the use of aqueous shunts with extraocular reservoir by clinicians for the management of adult OAG.

AAO Primary Open-Angle Glaucoma Preferred Practice Pattern (2020) states the indications for using aqueous shunts have been broadening, and these devices are being increasingly used in the surgical management of glaucoma. Several studies have compared aqueous shunts with trabeculectomy.

The American Glaucoma Society (Fellman 2020) published a position paper on microinvasive glaucoma surgery. The society supports efforts that facilitate patient access to these procedures, including more flexible regulatory pathways for new devices, expansion of the indications for already approved devices, and greater availability of information obtained by regulatory authorities.

The National Institute for Health and Care Excellence (NICE) issued interventional procedural guidance for trabecular stent bypass microsurgery for open angle glaucoma (NICE 2017). They report, "Current evidence on the safety of trabecular stent bypass microsurgery for open-angle glaucoma raises no major safety concerns. Evidence on efficacy is adequate in quality and quantity. Therefore, this procedure may be used."

NICE also issued procedural guidance for microinvasive subconjunctival insertion of trans-scleral gelatin stents for primary open-angle glaucoma (NICE 2018). They report, "evidence on the safety and efficacy of microinvasive subconjunctival insertion of a trans-scleral gelatin stent for primary open-angle glaucoma is limited in quantity and quality…NICE encourages further research into microinvasive subconjunctival insertion of a trans-scleral gelatin stent for primary open-angle glaucoma, including randomized studies. Further research should include details of patient selection and long-term outcomes."

REGULATORY STATUS

The first-generation Ahmed (New World Medical), Baerveldt (Advanced Medical Optics), Krupin (Eagle Vision), and Molteno (Molteno Ophthalmic) aqueous shunts received marketing clearance from the FDA between 1989 and 1993; modified Ahmed and Molteno devices were cleared in 2006. Their indication for use is "in patients with intractable glaucoma to reduce IOP where medical and conventional surgical treatments have failed."

The AquaFlow Collagen Glaucoma Drainage Device received premarket approval from the FDA in 2001 for the maintenance of sub-scleral space following nonpenetrating deep sclerectomy.

The Ex-PRESS Mini Glaucoma Shunt received Section 510(k) marketing clearance in 2003. The Ex-PRESS shunt is placed under a partial thickness scleral flap and transports aqueous fluid from the anterior chamber of the eye into a conjunctival filtering bleb.

Alcon (a division of Novartis) received FDA approval for its CyPass micro-stent in July 2016. CyPass is a micro-invasive glaucoma surgical (MIGS) device to treat patients with mild to moderate primary

OAG in conjunction with cataract surgery. The CyPass Micro-Stent is designed to control IOP by creating a drainage pathway from the anterior chamber to the suprachoroidal space. The FDA approval was based on the COMPASS Study, which included two-year follow-up of over 500 patients undergoing cataract surgery. On August 29, 2018, Alcon Research, LTD voluntarily issued a recall of the CyPass Micro-Stent and withdrew this product from the global market. The decision for the withdrawal was based on five-year post-surgery data from the COMPASS XT long-term safety study. The study demonstrated a clinically and statistically significant increase in corneal endothelial cell loss in patients who received the CyPass Micro-Stent. Based upon its review of this data, the FDA issued a Safety Communication notifying physicians and patients of the risk associated with this device and recommended that the use of this device be discontinued. The FDA recalled the CyPass device on August 28, 2018; therefore, it is no longer available for use.

On November 21, 2016, the FDA cleared Allergen's XEN Glaucoma Treatment System (consisting of the XEN45 Gel Stent and the XEN Injector). The XEN45 Gel Stent is a glaucoma implant designed to reduce IOP in eyes suffering from refractory glaucoma, including cases where previous surgical treatment has failed, in cases of primary OAG, and in cases of pseudo-exfoliative or pigmentary glaucoma with open angles that are unresponsive to maximal-tolerated medical therapy. The device creates a permanent channel through the sclera, allowing flow of aqueous humor from the anterior chamber into the subconjunctival space. The XEN45 Gel Stent is inserted via an ab interno approach, through a small corneal incision.

In 2012, the FDA approved the Glaukos Corporation's iStent Trabecular Micro-Bypass Stent, as indicated for use in conjunction with cataract surgery for the reduction of IOP in adult patients with mild to moderate OAG that is currently treated with ocular hypotensive medication.

In 2018, the iStent Inject device (Glaukos), was approved by the FDA through the 515(d) process for use in conjunction with cataract surgery for the reduction of IOP in adults with mild-to-moderate OAG currently treated with ocular hypotensive medication. The iStent Inject trabecular micro-bypass system contains two preloaded intraocular stents in the injector.

In August 2022 Glaukos' iStent Infinite was approved by the FDA to be inserted as a stand-alone procedure. iStent infinite consists of three micro stents on a single preloaded injector. The stents are designed to be implanted ab interno in three separate areas of the trabecular meshwork, creating a patent bypass through the trabecular meshwork into Schlemm canal to increase physiological aqueous outflow and reduce IOP.

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
0253T (E/I)	Insertion of anterior segment aqueous drainage device, without extraocular reservoir, internal approach, into the suprachoroidal space
0449T	Insertion of aqueous drainage device, without extraocular reservoir, internal approach, into the subconjunctival space; initial device
0450T	Insertion of aqueous drainage device, without extraocular reservoir, internal approach, into the subconjunctival space; each additional device (List separately in addition to code for primary procedure)
0474T (E/I)	Insertion of anterior segment aqueous drainage device, with creation of intraocular reservoir, internal approach, into the supraciliary space
0671T	Insertion of anterior segment aqueous drainage device into the trabecular meshwork, without external reservoir, and without concomitant cataract removal, one or more
66179	Aqueous shunt to extraocular equatorial plate reservoir, external approach; without graft
66180	Aqueous shunt to extraocular equatorial plate reservoir, external approach; with graft
66183	Insertion of anterior segment aqueous drainage device, without extraocular reservoir, external approach
66184	Revision of aqueous shunt to extraocular equatorial plate reservoir; without graft
66185	Revision of aqueous shunt to extraocular equatorial plate reservoir; with graft
66989	Extracapsular cataract removal with insertion of intraocular lens prosthesis (1-stage procedure), manual or mechanical technique (e.g., irrigation and aspiration or phacoemulsification), complex, requiring devices or techniques not generally used in routine cataract surgery (e.g., iris expansion device, suture support for intraocular lens, or primary posterior capsulorrhexis) or performed on patients in the amblyogenic developmental stage; with insertion of intraocular (e.g., trabecular meshwork, supraciliary, suprachoroidal) anterior segment aqueous drainage device, without extraocular reservoir, internal approach, one or more
66991	Extracapsular cataract removal with insertion of intraocular lens prosthesis (1 stage procedure), manual or mechanical technique (e.g., irrigation and aspiration or phacoemulsification); with insertion of intraocular (e.g., trabecular meshwork, supraciliary, suprachoroidal) anterior segment aqueous drainage device, without extraocular reservoir, internal approach, one or more

PRODUCT DISCLAIMER

- Services are contract dependent; if a product does not cover a service, medical policy criteria do not apply.
- If a commercial product (including an Essential Plan or Child Health Plus product) covers a specific service, medical policy criteria apply to the benefit.
- If a Medicaid product covers a specific service, and there are no New York State Medicaid guidelines (eMedNY) criteria, medical policy criteria apply to the benefit.
- If a Medicare product covers a specific service, and there is no national or local Medicare coverage decision for the service, medical policy criteria apply to the benefit.

POLICY HISTORY/REVISION

Committee Approval Dates

New: 1/20

Revised: 1/22, 1/24, 1/25, 7/26

Reviewed: 1/21, 1/23, 1/26

Date	Summary of Changes
8/1/2026	• Transitioned Aqueous Shunts/Stents for Glaucoma policy, 1370/20.000504

	to Lifetime HealthCare Companies policy template.
5/1/2025	• Updated Position Statement and Policy Considerations sections with new criteria and coding guidelines.
1/1/2024	• Added additional procedure codes 66989 and 66991. • Added Schocket Shunt to list of FDA- approved devices. • Added information on iSTENT Inject.
1/1/2022	• Under Policy Considerations, moved the statement that Cypass is non covered to the Exclusions section. • Removed from exclusions codes 0376T and 0450T as these are payment related and are on the Adjunct and Non-Standard Technology Payment Policy. • Effective 1/1/2022: Removed deleted code 0191T and updated with replacement code 0671T.
2/1/2020	• New – criteria in policy aligns with Medicare local coverage determination.

DESCRIPTIONS

Coronary plaque analysis (AI-QCT/AI-CPA) is an adjunctive tool for the quantification and characterization to assess the severity of coronary disease. This is derived from augmentative software analysis of data from a coronary computed tomographic angiography.

RELATED POLICIES/DOCUMENTS

Coronary Fractional Flow Reserve Using Computed Tomography, 1370/20.000511

POSITION STATEMENT

Coronary CT plaque quantification or coronary plaque analysis using data from CCTA is medically necessary when ALL of the following conditions exist:

POLICY NAME: **ARTIFICIAL INTELLIGENCE ENABLED CT BASED QUANTITATIVE CORONARY TOPOGRAPHY (AI-QCT) CORONARY PLAQUE ANALYSIS (AI-CPA)**

- The patient has acute or stable chest pain with no known CAD, prior to current workup, and is eligible for CCTA, **AND**

  After the CCTA is performed and interpreted, it indicates any of the risk categories below:
  - Intermediate risk;
  - CAD-RADS 1;
  - CAD-RADS 2;
  - CAD-RADS 3; **AND**

- Cardiac evaluation is negative or inconclusive for acute coronary syndrome

*The below details CAD-RADS stenosis scoring:
- CAD-RADS 0: No Stenosis
- CAD-RADS 1: < 25% stenosis
- CAD-RADS 2: 25-49% stenosis
- CAD-RADS 3: 50-69% stenosis
- CAD-RADS 4A: 70-99% stenosis in one or two vessels
- CAD-RADS 4B: 70-99% stenosis in three vessels or the left main artery
- CAD-RADS 5: 100% stenosis or total occlusion

EXCLUSIONS

Coronary CTA plaque quantification or coronary plaque analysis using data from CCTA is considered not medically necessary in ANY of the following clinical scenarios:

- Unstable coronary syndromes;
- In conjunction with invasive coronary catheterization;
- For the purpose of screening or disease surveillance;
- Within 30 days of a myocardial infarction;
- Current completed and interpreted CCTA documents **any** of the following results:
  - Normal CCTA;
  - CAD-RADS-0;
  - High-grade stenosis (> 70%);
  - CAD-RADS 4; **or**
  - CAD-RADS 5

MEDICAL POLICY

Medical Policy Title	**Assisted Reproductive Technologies**
Policy Number	**4.01.05**
Current Effective Date	**September 1, 2026**
Next Review Date	**December 2026**

Our medical policies are based on the assessment of evidence based, peer-reviewed literature, and professional guidelines. Eligibility for reimbursement is based upon the benefits set forth in the member's subscriber contract. (Link to Product Disclaimer)

Additional coverage for MEDICAID MANAGED CARE/HARP MEMBERS is addressed at the end of this document.

POLICY STATEMENT(S)

All Assisted Reproductive Technologies (ART), including but not limited to, in vitro fertilization (IVF) and artificial insemination, are contract dependent. All ART services must be provided by health care professionals who are qualified to provide such services, in accordance with the guidelines established and adopted by the American Society for Reproductive Medicine.

I. IVF, a type of ART, is considered **medically appropriate** when the following criteria are met:

   A. A diagnosis of infertility has been made, as defined by NYS Insurance Law §4303 (see Description V); **and**

   B. For individuals younger than 35 years of age, when a successful pregnancy has not been achieved after six to 12 cycles of assisted insemination (e.g., artificial insemination or therapeutic donor insemination);

   OR

   C. For individuals 35 years or older, when a successful pregnancy has not been achieved after three to six cycles of assisted insemination (e.g., artificial insemination or therapeutic donor insemination); **and**

   D. Failure of other reasonable, less expensive, and medically appropriate infertility treatments have not resulted in a successful pregnancy (e.g., treatment of ovulatory dysfunction, surgical treatment, etc.).

II. ART are **not medically necessary** for members who have undergone permanent birth control procedures (e.g. bilateral tubal ligation or vasectomy) as they do not meet the definition of infertility (refer to Policy Guideline VII).

III. ART are **not medically necessary** when the reversal of an elective sterilization does not restore fertility (e.g., a male member who remains azoospermic following the reversal of a prior elective sterilization), or either partner has undergone an elective sterilization in the past.

IV. IVF cycles initiated for the sole purpose of embryo banking are considered **not medically necessary**.

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

V. The following are considered **investigational**:

A. Assisted embryo hatching; (CPT 89253)

B. Hyaluronan binding assay (HBA);

C. Co-culture of embryos; (CPT 89251)

D. Sperm DNA integrity tests (e.g., sperm chromatin structure assay [SCSA], sperm chromatin dispersion test [SCD], sperm DNA fragmentation assay [SDFA], deoxynucleotidyl transferase-mediated deoxyuridine triphosphate-biotin nick end labeling [TUNEL], single cell electrophoresis assay [COMET]); **and**

E. Reproductive medicine (endometrial receptivity analysis [ERA]), RNA gene expression profile, 238 genes by next-generation sequencing, endometrial tissue, predictive algorithm reported as endometrial window of implantation (e.g., pre-receptive, receptive, post-receptive).

RELATED POLICIES

Corporate Medical Policy

11.01.03 Experimental or Investigational Services

Pharmacy Policies:

Infertility Medications, 1350/20.000567

POLICY GUIDELINE(S)

I. A cycle of assisted insemination consists of:

1. Monitoring for ova production and ovulation (e.g., lab tests and ultrasound);
2. Monitoring the uterine lining prior to insemination (e.g., ultrasound);
3. Preparation of fresh or frozen semen;
4. Intracervical (ICI) or intrauterine (IUI) insemination.

II. IVF is considered a cycle of treatment rather than a procedure at a single point in time.

A. An IVF cycle consists of:

1. taking medication to stimulate production of ova;
2. retrieval of ova;
3. fertilization of ova with sperm to create embryo(s);
4. fertilized embryo(s) transferred to the uterus;

OR

5. taking medication to prepare the endometrium

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

6. thawing and transfer of previously cryopreserved embryo(s)

III. All cryopreserved embryos that are suitable for transfer must be transferred prior to initiating another ovarian stimulation. Each transfer of an embryo(s) (either fresh or cryopreserved) is considered the completion of an IVF cycle.

IV. If a member undergoes ovarian stimulation, ova retrieval and fertilization, that does not result in any viable embryos, this will still constitute an IVF cycle.

V. Preimplantation genetic testing is not an indication for IVF.

VI. Peer-reviewed, published studies and professional society guidelines do not provide data concerning the appropriate number of cycles. Therefore, based upon specialty clinician input, when coverage is available for ART services and cycle limitations are not stipulated in the member's subscriber contract, the following will be considered medically appropriate:

A. Artificial insemination is limited to a lifetime maximum of six (6) cycles; and

B. IVF is limited to a lifetime maximum of three cycles. A "cycle" is considered all treatment that starts when: preparatory medications are administered with the intent of undergoing IVF with embryo transfer.

VII. There may be certain clinical situations where IVF could be considered first-line therapy for infertility (e.g., azoospermia, hysterosalpingogram demonstrating blocked fallopian tubes). These scenarios will be reviewed on a case-by-case basis for determination of medical necessity.

VIII. Methods of permanent birth control (e.g., bilateral tubal ligation or vasectomy) will not be considered causes of infertility.

IX. Infertility treatments for a partner who is not a member of the Health Plan are **ineligible for coverage.**

X. Gestational Carrier/Surrogacy/Use of Host Uterus: Ovarian stimulation and the retrieval of eggs are covered for individuals with a known medical cause of infertility, who meet the criteria for IVF, and have IVF benefit coverage. The implantation of eggs, donor sperm, or embryo(s) into a gestational carrier/surrogate/host uterus, regardless of their Health Plan member status is not covered. A Health Plan member's pregnancy, as a result of acting as a gestational carrier/surrogate/host uterus, would be covered per the gestational carrier/surrogate/host uterus Health Plan member's benefit contract.

XI. Reciprocal IVF: In cases where both the egg donor and gestational carrier are both uterus and/or ovary bearing individuals and intended parents, ovarian stimulation and egg retrieval are covered dependent on the egg donor's IVF benefit contract. Both the egg donor and gestational carrier must meet criteria in policy statement I to proceed with IVF unless failure of other medically appropriate infertility treatments have not resulted in a successful pregnancy (e.g., treatment of ovulatory dysfunction, surgical treatment, use of donor sperm for assisted insemination, etc.).

XII. Fertility Preservation: Refer to Description V.B.

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

XIII. Clinical contraindications to infertility treatment include:

A. Use of prescription medication detrimental to or contraindicated for pregnancy; or

B. Any coexisting medical conditions that place the patient and/or fetus at unacceptable risk (e.g., uncontrolled diabetes mellitus, poorly controlled hypertension, clinically severe obesity).

XIV. Contract Exclusions and Limitations:

A. IVF and other forms of ART are contract-dependent. Please refer to the terms of the member's contract or service agreement prior to review.

B. The following services may be **ineligible for coverage**:

1. Procurement of donor sperm or ova;
2. Cryopreservation of eggs, sperm or semen, embryo, oocyte, testicular or ovarian reproductive tissue.
3. Monitoring and storage of cryopreserved eggs, embryo, oocyte, sperm or semen, testicular or ovarian reproductive tissue or previously frozen embryos;
4. Thawing of cryopreserved eggs, embryo, oocyte, sperm or semen, testicular or ovarian reproductive tissue;
5. Cloning services and procedures;
6. Reversal of tubal ligations;
7. Reversal of vasectomies;
8. Travel expenses.

DESCRIPTION

The American Society for Reproductive Medicine (ASRM, 2023) has defined infertility as a "disease, condition, or status characterized by the inability to achieve a successful pregnancy based on a patient's medical, sexual, and reproductive history, age, physical findings, diagnostic testing, or any combination of those factors; or the need for medical intervention, including, but not limited to, the use of donor gametes or donor embryos in order to achieve a successful pregnancy either as an individual or with a partner; or in patients having regular, unprotected intercourse and without any known etiology for either partner suggestive of impaired reproductive ability, evaluation should be initiated at 12 months when the female partner is under 35 years of age and at six months when the female partner is 35 years of age or older. Nothing in this definition shall be used to deny or delay treatment to any individual, regardless of relationship status or sexual orientation."

I. There are many causes of infertility, and may include:

A. Ovulatory dysfunctions such as: amenorrhea, oligoovulation, oligomenorrhea, or hyperprolactinemia;

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

B. Uterine anomalies and abnormalities, such as unicornate, septate or bicornate uteri, endometrial polyps, submucous myomas, or synechiae;

C. Peritoneal factors, such as endometriosis or pelvic/adnexal adhesions;

D. Anatomic tubal damage or disease;

E. Cervical factors, such as abnormal cervical mucus production or poor sperm-mucous interaction;

F. Azoospermia - the absence of spermatozoa/sperm;

G. Oligospermia - low sperm count;

H. Low sperm motility; and

I. Teratospermia - abnormal semen morphology.

II. ART procedures involve the laboratory handling of human ova, sperm and embryos in response to diagnosed infertility. ART procedures include, but are not limited to, the following:

A. Assisted insemination procedures in which fertilization takes place within the human body:

1. Artificial Insemination - a process involving the non-coital introduction of sperm into the cervical canal (intracervical) or uterine cavity (intrauterine), to produce conception. Intrauterine insemination can be used with ovulation stimulation.

2. Therapeutic Donor insemination- a process that requires the use of donor sperm, for assisted insemination.

B. Procedures in which fertilization takes place outside the human body:

1. In-Vitro Fertilization (IVF) - a process in which mature ova are removed from the ovaries by various methods, placed in a laboratory medium with sperm, and incubated. The embryo(s) are then placed into the uterus through the cervix.

2. Cryopreserved Embryo Transfer (CET) - the transfer of embryo(s) that were previously cryopreserved (frozen) in the laboratory, thawed, and then transferred into the uterus.

3. Intracytoplasmic Sperm Injection (ICSI) - the micromanipulation of sperm performed in a laboratory, and involving the injection of a single sperm directly into the cytoplasm of a mature ovum using a microinjection pipette.

C. Natural oocyte retrieval (NORIVF) - the harvesting of ova from the ovary following natural ovulation (ovulation without hormone therapy).

III. Co-culture of embryos involves an effort to improve the culture media for embryos, so that a greater proportion of embryos will reach the blastocyst stage and, hopefully, improve the implantation and pregnancy rate. In the co-culture procedure, "helper" cells are grown along with the developing embryo. A variety of co-culture techniques have been investigated, involving the use of feeder cell layers derived from a range of tissues (e.g., human oviducts, fetal bovine uterine or oviduct cells), to established cell lines.

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

IV. Assisted hatching involves a procedure intended to thin or perforate the zona pellucida. It has been investigated as a method of improving the implantation and subsequent pregnancy rates following IVF. Several techniques have been used to mechanically or chemically weaken the zona pellucida, including drilling, dissection, application of acid solutions or proteinases, and laser energy.

V. New York Insurance Law §4303 defines infertility as "a disease or condition characterized by the incapacity to impregnate another person or to conceive, due to the failure to establish a clinical pregnancy after 12 months of regular, unprotected sexual intercourse or therapeutic donor insemination, or after six months of regular unprotected sexual intercourse or therapeutic donor insemination for a female 35 years of age or older." The law also mandates the following benefits for treatment of infertility, under most insured managed care and indemnity health plans.

   A. Policies that provide coverage of hospital care or surgical and medical care must cover the following services:

      1. Services in relation to surgical and medical procedures to correct malformation, disease or dysfunction resulting in infertility; and
      2. Services in relation to diagnostic tests and procedures necessary:
         a. To determine infertility; or
         b. In connection with any surgical or medical treatments or prescription drug coverage included in the mandate.

   B. In 2020, the law was expanded to require coverage of the following fertility preservation services under most insured managed care and indemnity health plans.

      1. Standard fertility preservation services when a medical treatment is necessary to correct malformation, disease or dysfunction that may, directly or indirectly, cause iatrogenic infertility; or when fertility is impaired by surgery, radiation, chemotherapy or other medical treatment affecting reproductive organs or processes. Standard fertility preservation services include the collecting, preserving, and storage of ova or sperm.
      2. Basic infertility treatments (e.g., intrauterine insemination procedures) must be provided to individuals who are unable to conceive due to their sexual orientation or gender identity.
      3. Standard fertility preservation services will be covered for individuals whose medical treatment for gender dysphoria will directly or indirectly result in iatrogenic infertility.
      4. Cryopreservation will be covered in connection with an intended IVF procedure if medically necessary, until the three covered IVF cycles are provided.

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

Under the statute, fertility preservation services solely for the purpose of delaying reproduction are not eligible for coverage. The statute does not require coverage of procedures to reverse a previous voluntary sterilization procedure or infertility treatment for a person in connection with such reversal.

C. Policies providing coverage for prescription drugs that also cover hospital or medical/surgical services must provide coverage for FDA approved drugs for the diagnosis and treatment of infertility.

1. Also excluded from the mandate are medical or surgical services or procedures that are deemed experimental in accordance with the guidelines and standards of the American College of Obstetricians and Gynecologists (ACOG) and the American Society for Reproductive Medicine (ASRM), which state: "A procedure for the treatment of infertility is considered experimental until there is adequate scientific evidence of safety and efficacy from appropriately designed, peer-reviewed, published studies by different investigator groups."
2. The diagnosis of infertility must be made, and treatment must be prescribed by a physician and documented in plan of care.
3. The determination of appropriate candidates for the treatment of infertility, and the identification of the required training, experience and other standards for health care providers who wish to diagnose and treat infertility, are governed by the standards and guidelines adopted by ACOG and ASRM.

VI. Endometrial Receptivity Analysis (ERA)-ERA has been proposed for women with repeat implantation failures. The goal of ERA is to identify an individual's window of implantation (WOI) during an IVF transfer cycle. This requires a biopsy of the endometrium during a mock transfer cycle of IVF, where the individual undergoes the preparatory steps of IVF, including medications. No transfer of embryos occurs at this time. After endometrial biopsy, the receptivity is measured by the presence of exogenous and/or endogenous progesterone after oestradiol priming and is analyzed through next-generation sequencing to identify each endometrial stage: proliferative, pre-receptive, receptive, and post-receptive. The identification of the receptive stage might push forward or back the date of embryo transfer.

VII. Surrogacy/Gestational Carrier/Host Uterus- Traditional surrogacy is defined as the use of an individual who has a biological connection to the intended parents to receive eggs, or donor sperm to have a biologically related child when infertility is diagnosed. This can be accomplished through assisted insemination or IVF. A gestational carrier is a third-party individual without any familial/biological connection to intended parents who are infertile, who agrees to act as a host uterus, to receive eggs, donor sperm, or embryo(s) to achieve and carry a pregnancy. This is typically accomplished via IVF, unless the gestational carrier also provides the donor eggs, which would allow for attempts at assisted insemination.

VIII. Reciprocal IVF is a process that allows two uterus-bearing people to participate biologically in a pregnancy in which both the egg donor and gestational carrier are the intended parents.

SUPPORTIVE LITERATURE

This policy is based upon Health Plan contract benefits and is intended to clarify those benefits.

Assisted Hatching (AH)

The AH procedure has been utilized by clinicians, but this practice is not strongly supported by the evidence. In 2012, Carney et al published an update of a 2009 Cochrane systematic review and meta-analysis on AH, to determine the effect of AH of embryos from assisted conception on live birth and multiple pregnancy rates. Randomized, controlled trials (RCTs) of AH (mechanical, chemical or laser disruption of the zona pellucida prior to embryo replacement) versus no AH that reported live birth or clinical pregnancy were reviewed for quality assessments and data extraction. Thirty-one trials reported clinical pregnancy data, including 1992 clinical pregnancies in 5728 women. The authors concluded that, while AH does appear to offer a significantly increased chance of achieving a clinical pregnancy, the extent to which it may do so only just reaches statistical significance; the "take home" baby rate was still not proven to be increased by AH; and the included trials provided insufficient data to investigate the impact of AH on several important outcomes and most trials still failed to report on live birth rates. The current data do not support the use of AH as a routine practice to improve IVF outcomes.

A 2021 Cochrane review, by Lacey et al, was conducted to determine the effects of AH of embryos services from assisted conception on live birth and multiple pregnancies. The review included 39 RCTs, comprised of 7,249 women and 2,486 clinical pregnancies. Authors concluded that routine use of AH is not supported by strong evidence. The effects of AH on live birth rates are uncertain and AH may lead to increased risk of multiple pregnancy. AH may offer a slightly increased chance of achieving a clinical pregnancy, but data quality was low grade. Alteri et al (2024) published a randomized controlled trial that evaluated whether laser-mediated assisted hatching performed on vitrified/warmed blastocysts before embryo transfer can improve live birth rate. 698 participants met the inclusion criteria and were randomized: 352 patients were assigned to the AH arm and 346 to the control arm. Inclusion criteria were women at oocyte retrieval aged greater than or equal to 40 years, first or second frozen cycle using vitrified blastocysts, first or second oocyte retrieval, and collapsed blastocysts vitrified after laser-assisted artificial shrinkage. Patients transferring frozen blastocysts obtained from frozen oocytes could be included. Patients were not enrolled in the presence of any of the following exclusion criteria: preimplantation genetic testing cycle, body mass index (BMI) of >35 kg/m2, uterine abnormalities (e.g., adenomyosis, submucous myoma, septate uterus, and endometrial polyps), unoperated hydrosalpinx, and severe male factor (use of surgically retrieved spermatozoa). The primary outcome was the live birth rate. Secondary end points included clinical pregnancy, miscarriage, multiple pregnancies, preterm births, obstetric and neonatal complications, and congenital anomalies. Of the participants, 105 (29.8%) and 101 (29.2%), respectively, achieved a live birth after treatment. The relative risk of live birth in patients with vitrified/warmed blastocysts treated with AH was 1.02 (95% confidence interval, 0.86–1.19). Exploratory subgroup analyses for women's age, recruiting centers, indications for in vitro fertilization, method of insemination, blastocyst quality, and days of blastocyst development failed to highlight any clinical situation that

could benefit from AH in thawed blastocysts. Authors concluded, in patients undergoing frozen embryo transfer with vitrified/warmed blastocysts, laser AH does not improve the live birth rate. Further studies are required to rule out milder but potentially interesting benefits in specific subgroups of patients.

The most recently updated guideline from the American Society of a Reproductive Medicine that addresses AH (2022) states, "In studies evaluating pregnancy rates in an unselected patient population, there is moderate evidence that live birth rates are not significantly different between embryos that have undergone AH vs. those that have not. In patients with a poor prognosis, the data are mixed regarding improvement in live birth rates with laser-AH." The data is insufficient to make recommendations regarding the use of laser-AH in frozen embryo transfer cycles (Strength of evidence: B; strength of recommendation: moderate).

Co-Culture of Embryos

There is no standardized method of co-culture, and few clinical trials have evaluated outcomes. Most studies have not found improved implantation or pregnancy rates after co-culture. One 2015 randomized, controlled trial reported on a novel co-culture method, and an interim analysis of the trial found a higher clinical pregnancy rate with co-culture than with standard practice control group. Additional studies are needed to evaluate this novel co-culture technique. No studies have reported on the impact of co-culture on live birth rates.

ERA

To date, only one RCT has been identified comparing ERA (personalized embryo transfer [pET]) with IVF conducted with frozen (FET) or fresh embryo transfer (ET) (Simon et al 2020). The study included 458 patients over 16 centers, who were less than 37 years of age undergoing IVF with blastocyst transfer. The study reported significantly higher cumulative pregnancy and live birth rates but there were several limitations. The intention to treat analysis demonstrated comparable clinical outcomes across the three transfer types, individuals with repeated infertility failures were excluded, and there was a 50% drop out rate causing the study to be underpowered. The evidence does not demonstrate that personalized embryo transfer utilizing the ERA test improves the net health outcome.

PROFESSIONAL GUIDELINE(S)

The American Urological Association (AUA), in collaboration with the American Society for Reproductive Medicine, released the 2024 Male Infertility Guideline. This guideline provides a comprehensive framework for evaluating and managing the male partner in an infertile couple. It emphasizes the importance of obtaining a thorough history and conducting a physical examination, followed by appropriate diagnostic testing when necessary. The guideline also covers medical treatments, surgical techniques, and the use of intrauterine insemination and assisted reproductive technologies to ensure optimal patient care.

The American Society for Reproductive Medicine (ASRM) has several committee opinions that address assistive reproductive technologies (see reference section). ASRM does not recommend ERA, AH or co-culture of embryos for routine IVF patients.

The American College of Obstetricians and Gynecologists (ACOG) committee opinion number 671 (reaffirmed 2020) does not recommend ERA, AH, or co-culture for routine IVF patients. Their guidance focuses on patient safety and counseling rather than endorsing adjunctive lab techniques.

REGULATORY STATUS

The United States Food and Drug Administration (FDA) is responsible for ensuring the safety, efficacy, and quality of drugs sold in the United States. This includes both prescription and over-the-counter medications. Refer to the FDA Drug website. Available from: https://www.fda.gov/drugs [accessed 2025 Nov 6]

The FDA maintains information for consumers and health professionals on new drug warnings and other safety information, drug label changes, and shortages of medically necessary drug products. Available from: Drug Safety and Availability [accessed 2025 Nov 6]

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
58321	Artificial insemination; intra-cervical
58322	Artificial insemination; intra-uterine
58323	Sperm washing for artificial insemination
58970	Follicle puncture for oocyte retrieval, any method
58974	Embryo transfer, intrauterine
58976	Gamete, zygote, or embryo intrafallopian transfer, any method
89250	Culture of oocyte(s)/embryo(s), less than 4 days

Code	Description
89251 (E/I)	Culture of oocyte(s)/embryo(s), less than 4 days; with co-culture of oocyte(s)/embryos
89253 (E/I)	Assisted embryo hatching, microtechniques (any method)
89254	Oocyte identification from follicular fluid
89255	Preparation of embryo for transfer (any method)
89257	Sperm identification from aspiration (other than seminal fluid)
89261	Sperm isolation; complex prep (e.g. Percoll gradient, albumin gradient) for insemination or diagnosis with semen analysis
89264	Sperm identification from testis tissue, fresh or cryopreserved
89268	Insemination of oocytes
89272	Extended culture of oocyte(s)/embryo(s), 4-7 days
89280	Assisted oocyte fertilization, microtechnique; less than or equal to 10 oocytes
89281	Assisted oocyte fertilization, greater than 10 oocytes
89258	Cryopreservation; embryo(s)
89259	Cryopreservation; sperm
89335	Cryopreservation, reproductive tissue, testicular
89337	Cryopreservation, mature oocyte(s)
89342	Storage, (per year); embryo(s)
89343	Storage, (per year); sperm/semen
89344	Storage, (per year); reproductive tissue, testicular/ovarian
89346	Storage, (per year); oocyte(s)
89352	Thawing of cryopreserved; embryo(s)
89353	Thawing of cryopreserved; sperm/semen, each aliquot

Code	Description
89354	Thawing of cryopreserved; reproductive tissue, testicular/ovarian
89356	Thawing of cryopreserved; oocytes, each aliquot
89398	Unlisted reproductive medicine laboratory procedure

CENTERS FOR MEDICARE AND MEDICAID SERVICES (CMS)

Effective October 1, 2019, Medicaid Managed Care (MMC) and Health and Recovery Plan (HARP) benefits will include medically necessary ovulation enhancing drugs and medical services related to prescribing and monitoring the use of such drugs for individuals 21 through 44 years of age experiencing infertility.

For Medicaid purposes, infertility is a condition characterized by the incapacity to conceive, defined by the failure to establish a clinical pregnancy after:

1. Twelve months of regular, unprotected sexual intercourse for individuals 21 through 34 years of age, or
2. Six months for individuals 35 through 44 years of age.

Infertility benefits include:

1. Office visits;
2. Hysterosalpingograms;
3. Pelvic ultrasounds;
4. Blood testing;
5. Ovulation enhancing drugs.

The ovulation enhancing drugs included in the Medicaid formulary are:

1. Bromocriptine;
2. Clomiphene Citrate;
3. Letrozole;
4. Tamoxifen.

Benefits will be limited to coverage for three (3) cycles of treatment per lifetime.

October 2019 Medicaid Update Bulletin. Available from: https://www.health.ny.gov/health_care/medicaid/program/update/2019/2019-06.htm#ovulation [accessed 2025 Nov 06].

PRODUCT DISCLAIMER

- Services are contract dependent; if a product does not cover a service, medical policy criteria do not apply.
- If a commercial product (including an Essential Plan or Child Health Plus product) covers a specific service, medical policy criteria apply to the benefit.
- If a Medicaid product covers a specific service, and there are no New York State Medicaid guidelines (eMedNY) criteria, medical policy criteria apply to the benefit.
- If a Medicare product covers a specific service, and there is no national or local Medicare coverage decision for the service, medical policy criteria apply to the benefit.

POLICY HISTORY/REVISION	
Committee Approval Dates	
New: 11/89 **Revised**: 02/93, 05/94, 03/95, 08/95, 06/96, 12/97, 09/98, 11/99, 05/00, 04/02, 11/02, 02/03, 1/04, 01/05, 11/05, 11/06, 04/07, 03/08, 09/08, 09/09, 11/09, 09/10, 09/11, 09/13, 09/14, 09/15, 11/15, 11/16, 07/17, 09/18, 09/19, 01/20, 03/20, 07/20, 09/20, 01/21, 3/21, 5/21, 7/21, 9/21, 11/21, 5/22, 9/22, 9/23, 11/23, 3/24, 7/24, 11/24, 1/25, 7/25, 9/25, 5/26 **Reviewed**: 08/94, 09/12, 09/16, 09/17	
Date	**Summary of Changes**
9/1/2026	• Transitioned Infertility Services policy, 1370/20.000050 to Lifetime HealthCare Companies policy template.
9/1/2025	• Updated information throughout the policy referencing new pharmacy policy, Infertility Medications, 1350/20.000567.
2/1/2025 * No change to effective date of policy	• Removed reference to Avalon Healthcare Solutions and updated with current genetic vendor (HealthHelp).
2/1/2025	• Under exclusions added: Endometrial Receptivity Analysis (ERA) test, 0253U.
10/1/2024 *No change to effective date of policy	• Under IUI- removed cycle limits. • Under Advanced Infertility, updated verbiage for storage of ova/sperm.
10/1/2024	• Added pertinent codes to Procedure Codes Section
7/1/2024	• Under Fertility Preservation section added statement regarding collecting more than one sample and under exclusions added endometrial scratching/injury to improve uterine/endometrial receptivity.
3/1/2024	• Under the IVF section added the following statement: Prior authorization will need to be obtained for each individual cycle.

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

12/1/2023	• Clarified verbiage for storage of oocytes/embryos. • Added statement on utilization of frozen embryos/oocytes prior to fresh retrieval for IVF. • Added exclusion for single members who have not demonstrated infertility.
9/1/2023	• Under Medicaid section: • removed reference to Clomiphene for Female Infertility policy as this policy is now obsolete. • added verbiage that effective 4/1/23 pharmacy benefit is administered by NYRx.
9/1/2022 * No change to effective date	• Added examples of conditions that may preclude a trial of artificial insemination/intrauterine insemination.
9/1/2022	• Removed the following statement as all providers are required to obtain prior authorization: Infertility services require authorization when rendered by providers other than the enrollee's primary care physician or designated obstetrical/gynecological practitioner.
01/18/2022	• Updated verbiage for preimplantation genetic testing: coverage for PGT in accordance with criteria outlined in policy, M2039 – Pre-Implantation Genetic Testing. Prior authorization is required through Avalon Healthcare Solutions (see Genetics & Molecular Diagnostics/1370/20.000210 policy).
12/1/2021	• Under Fertility Preservation Services and Exclusions sections, clarified fertility preservation benefit of embryos for members who are approved for advanced infertility services.
11/1/2021 *No change to effective date	• Under Advanced Infertility, updated criteria for eligibility of IVF services.

5/1/2021* *No change to effective date	• As result of DFS Circular Letter dated February 2021, updated Position Statement to include enrollees who are identified as gender non-binary or transgender, or who are a same-sex couple, which removes the "waiting period" of meeting the definition of infertility and removed information about surrogacy from the Exclusions section.
5/1/2021	• Added section to address coverage for intra-cytoplasmic sperm injection (ICSI). • Removed termed code 0058T and replaced with 89398.
3/11/2020 (Effective date on policy remains the same)	• Added infertility treatment in connection with reversal of a previous voluntary sterilization to the Exclusions section.
3/11/2020	• Added section to address preimplantation genetic testing relating to IVF procedure.
1/1/2020	• Added section on advanced infertility services and updated fertility preservation services section in accordance with NYS mandate effective 1/1/20.

MEDICAL POLICY

Medical Policy Title	**Autologous Hematopoietic Stem Cell Transplantation (Auto-HSCT)**
Policy Number	**7.02.03**
Current Effective Date	**July 1, 2026**
Next Review Date	**February 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Autologous hematopoietic stem cell transplant (auto-HSCT) is considered **medically appropriate** when **ALL** of the following criteria are met:

A. Candidates have met the transplanting institution's selection criteria;

B. The multidisciplinary team has evaluated the individual and recommends treatment (see policy guidelines for required documentation); **and**

C. The individual meets the following indication-specific criteria:

Blood/Plasma Cancers

1. Acute Promyelocyte Leukemia
   a. Adult ≥ age 18; in the following disease state:
      i. CR2, in molecular remission
   b. Child ≤ age 17; in the following disease state:
      i. Relapse;
2. Multiple Myeloma
   a. Adult ≥ age 18; in any of the following disease states:
      i. Initial response;
      ii. Sensitive relapse;
      iii. Refractory;
3. Plasma Cell Leukemia
   a. Adult ≥ age 18;
4. Amyloid Light-chain Amyloidosis
   a. Adult ≥ age 18

5. POEMS Syndrome
    a. Adult ≥ age 18
6. Relapse after Autologous Transplant
    a. Adult ≥ age 18
7. Hodgkin Lymphoma
    a. Adult ≥ age 18; in **any** of the following disease states:
        i. Primary refractory, sensitive;
        ii. First relapse, sensitive; **or**
        iii. Second or greater relapse
    b. Child ≤ age 17; in **any** of the following disease states:
        i. Primary refractory, sensitive;
        ii. First relapse, sensitive; **or**
        iii. Second or greater relapse;
8. Diffuse Large B-cell Lymphoma
    a. Child ≤ age 17; in **any** of the following disease states:
        i. Primary refractory, sensitive;
        ii. First relapse, sensitive; **or**
        iii. Second or greater relapse;
    b. Adult ≥ age 18; and in **any** of the following disease states
        iv. Primary refractory, sensitive;
        v. First relapse, sensitive; **or**
        vi. Second or greater relapse;
9. High-grade B cell Lymphoma, with MYC and BCL2 or BL6 rearrangements:
    a. Adult ≥ age 18; and in **any** of the following disease states
        i. CR1 (positron emission tomography negative);
        ii. Primary refractory, sensitive;
        iii. First relapse, sensitive; **or**
        iv. Second or greater relapse;
10. Primary Central Nervous System Lymphoma
    a. Adult ≥ age 18; in **either** of the following disease states:

i. CR1/first partial remission (consolidation); **or**
ii. Relapse, sensitive;

11. Follicular Lymphoma
    a. Adult ≥ age 18; in **any** of the following disease states:
        i. Primary refractory, sensitive;
        ii. First relapse, sensitive (including POD24);
        iii. Second or greater relapse; **or**
        iv. Transformation to high-grade lymphoma;
12. Mantle Cell Lymphoma
    a. Adult ≥ age 18; in **any** of the following disease states:
        i. First partial remission;
        ii. Primary refractory, sensitive;
        iii. First relapse, sensitive; **or**
        iv. Second or greater relapse;
13. T-Cell non-Hodgkin Lymphoma
    a. Adult ≥ age 18; in **any** of the following disease states:
        i. CR1/first partial remission;
        ii. Primary refractory, sensitive;
        iii. First relapse, sensitive; **or**
        iv. Second or greater relapse;
    b. Child ≤ age 17; in **any** of the following disease states:
        i. CR1, standard or high risk;
        ii. CR2; **or**
        iii. Third complete remission with additional therapy (CR3+);
14. Burkitt Lymphoma
    a. Adult ≥ age 18: in the following disease state:
        i. First or greater relapse, sensitive;
    b. Child ≤ age 17; in the following disease state:
        i. First or greater relapse, sensitive;
15. Cutaneous T Cell Lymphoma

a. Adult ≥ age 18; in relapse;

16. Lymphoplasmacytic lymphoma/Waldenstrom macroglobulinemia
    a. Adult ≥ age 18; in **any** of the following disease states:
        i. Primary refractory, sensitive; **or**
        ii. First or greater relapse, sensitive;
17. Plasmablastic Lymphoma
    a. Adult ≥ age 18; in relapse;
18. Chronic Lymphocytic Leukemia
    a. Adult ≥ age 18; in **any** of the following disease states:
        i. T cell prolymphocytic leukemia;
        ii. B cell, prolymphocytic leukemia; **or**
        iii. Transformation to high-grade lymphoma;

<u>Solid Tumors</u>

19. Germ cell tumors
    a. Adult ≥ age 18; in **either** of the following disease states:
        i. Relapse; **or**
        ii. Refractory;
    b. Child ≤ age 17; in **either** of the following disease states:
        i. Relapse; **or**
        ii. Refractory;
20. Neuroblastoma
    a. Child ≤ age 17; in **either** of the following disease states:
        i. High risk; **or**
        ii. Relapse;
21. Wilms Tumor
    a. Child ≤ age 17; in relapse;
22. Osteosarcoma
    a. Child ≤ age 17; in relapse;
23. Ewing's sarcoma
    a. Adult ≥ age 18; high risk;

b. Child ≤ age 17; in **either** of the following disease states:
    i. High risk; **or**
    ii. Relapse;

24. Medulloblastoma
    a. Adult ≥ age 18; high risk or recurrent;
    b. Child ≤ age 17; high risk or recurrent;
25. Pediatric brain tumors when **both** of the following criteria are met:
    a. High risk (e.g. rhabdoid tumors); **and**
    b. The intent is to avoid craniospinal radiation therapy;

Non-Malignant Conditions

26. Multiple Sclerosis (MS)
    a. Adult ≥ age 18; and ≤ 45 years; when **all** of the following criteria are met:
        i. Individual has a diagnosis of relapsing-remitting or secondary progressive MS;
        ii. Two (2) or more clinical relapses or one (1) relapse and MRI gadolinium-enhancing lesion(s) at an independent time point in the previous 12 months;
        iii. Continued disease activity despite use of one or more FDA-approved disease-modifying therapies (e.g., interferons, glatiramer acetate natalizumab, fingolimod, dethyl fumarate); **and**
        iv. Expanded Disability Status Scale (EDSS) score between 2.0 and 5.5 or less;
27. Systemic Sclerosis
    a. Adult ≥ age 18 with **either** of the following:
        i. Pulmonary Involvement with **both**:
            a) Active interstitial lung disease (i.e., bronchoalveolar cell composition or ground-glass opacities on computed tomography of the chest); **and**
            b) Forced vital capacity or a diffusing capacity of the lung for carbon monoxide of less than 70% of the predicted value;

            OR

            c) Renal involvement with previous scleroderma-related renal disease;
    b. Child ≤ age 17
28. Juvenile Rheumatoid Arthritis;
    a. Child ≤ age 17.

II. Autologous HSCT is considered **investigational** for all other indications.

RELATED POLICIES

Corporate Medical Policy

7.02.02 Allogeneic Hematopoietic Stem Cell Transplantation (HSCT)

7.02.11 Chimeric Antigen Receptor T-cell (CAR-T) Therapy

11.01.03 Experimental or Investigational Services

POLICY GUIDELINE(S)

Each individual considered for autologous stem cell transplant will be evaluated by the transplant center for potential difficulties that would complicate and diminish the success of transplantation. Consideration will be given to the patient's risk of death without transplantation, along with the presence and severity of potential contraindications to transplantation.

I. Required documentation from the multidisciplinary team that includes the individual's eligibility and risk for autologous stem cell transplant should include:

   A. Clinical Evaluation

      1. Confirmation of diagnosis;
      2. Identification of co-morbidities;
      3. Current assessment of co-morbidities;
      4. Management of co-morbidities;
      5. Consult notes (if applicable);

   B. Psycho-Social Evaluation:

      1. Identification of stressors (e.g., family support, noncompliance issues, motivational issues, alcohol, or smoking/substance abuse).

   C. Performance Status:

      1. Karnofsky performance score;
      2. Palliative Performance Scale (PPS) score;
      3. Eastern Cooperative Oncology Group (ECOG) performance status; or
      4. Lansky Play-Performance Scale (for age 1 to 16 years)

   D. Oral Health Evaluation

   E. Lab Tests:

      1. CBC;
      2. Metabolic profile;

F. Cardiac Assessment:
   1. 12 Lead EKG;
   2. Echo or Muga Scan

G. Pulmonary Assessment:
   1. Chest x-ray;
   2. Pulmonary function tests (PFTs) for high-risk for respiratory failure (COPD, emphysema, a-1-antritrypsin deficiency, hepatopulmonary syndrome, or significant smoking history);

H. Age-Appropriate Screening Tests:
   1. Please refer to the U.S. Preventive Services Task Force (USPSTF) website for list of age-appropriate screening guidelines. https://uspreventiveservicestaskforce.org/uspstf/ [accessed 2025 Nov 24]

DESCRIPTION

In auto-HCT a portion of the patient's own stem cells are re-infused intravenously to rescue the patient by re-establishing his/her bone marrow which has been eradicated after high dose chemotherapy and/or total body irradiation has been given to destroy the malignant cells. Utilization of one's own cells avoids immunologic incompatibilities that can be seen with allogeneic stem cell transplants. This also permits subsequent engraftment and repopulation of the bone marrow with normal hematopoietic stem cells obtained from the patient before undergoing bone marrow ablation. Therefore, auto-HCT is typically performed as consolidation therapy when the patient's disease is in complete remission. Patients who undergo auto-HCT are also susceptible to chemotherapy-related toxicities and opportunistic infections before engraftment.

Disability Scores

I. The Karnofsky performance status score describes a patient's functional status as a comprehensive 11-point scale correlating to percentage values ranging from 100% (no evidence of disease, no symptoms) to 0% (death). Adapted from Peus, et al 2013:

A: Able to carry on normal activity and to work. No special care is needed.	100	Normal, no complaints, no evidence of disease.
	90	Able to carry on normal activity, minor signs or symptoms of disease.
	80	Normal activity with effort, some signs, or symptoms of disease.
B: Unable to work. Able to live at home, care for most personal needs.	70	Cares for self, unable to carry on normal activity or to do active work.

A varying degree of assistance is needed.	60	Requires occasional assistance but is able to care for most of personal needs.
	50	Requires considerable assistance and frequent medical care.
C: Unable to care for self. Requires equivalent of institutional or hospital care. Disease may be progressing rapidly.	40	Disabled, requires special care and assistance. [In bed more than 50% of the time]
	30	Severely disabled, hospitalization is indicated although death not imminent. [Almost completely bedfast]
	20	Very ill, hospitalization and active supportive treatment necessary. [Totally bedfast and requiring extensive nursing care by professionals and/or family]
	10	Moribund, fatal processes progressing rapidly. [Comatose or barely arousable]
	0	Dead.

II. Palliative Performance Scale (PPS) score; adapted from Fast Facts and Concepts (Wilner and Arnold 2004):

Percentage	**Ambulation**	**Activity Level/Evidence of Disease**	**Self-Care**	**Intake**	**Level of Consciousness**
100	Full	Normal No Disease	Full	Normal	Full
90	Full	Normal Some Disease	Full	Normal	Full
80	Full	Normal with Effort Some Disease	Full	Normal or Reduced	Full
70	Reduced	Can't do normal job or	Full	As above	Full

		work Some Disease			
60	Reduced	Can't do hobbies or housework Significant Disease	Occasional Assistance Needed	As above	Full or confusion
50	Mainly sit/lie	Can't do any work Extensive Disease	Considerable Assistance Needed	As above	Full or Confusion
40	Mainly in bed	As above	Mainly Assistance	As above	Full or Drowsy or Confusion
30	Bed Bound	As above	Total Care	Reduced	As above
20	Bed Bound	As above	As above	Minimal	As above
10	Bed Bound	As above	As above	Mouth care only	Drowsy or coma
0	Death	-	-	-	-

III. Eastern Cooperative Oncology Group (ECOG) performance status; adapted from ECOG-ACRIN Cancer Research group:

Grade	ECOG PERFORMANCE STATUS
0	Fully active, able to carry on all pre-disease performance without restriction
1	Restricted in physically strenuous activity but ambulatory and able to carry out work of a light or sedentary nature, e.g., light housework, office work
2	Ambulatory and capable of all selfcare but unable to carry out any work activities; up and about more than 50% of waking hours
3	Capable of only limited selfcare; confined to bed or chair more than 50% of waking hours

4	Completely disabled; cannot carry on any selfcare; totally confined to bed or chair
5	Dead

IV. Lansky Play-Performance Scale (for age 1 to 16 years)

The Lansky play-performance scale is used for children aged 1-16 with any type of malignancy. It is typically rated by parents based on their child's activity over the past week. Adapted from: Performance status | HemOnc.org - A Hematology Oncology Wiki [accessed 2025 Nov 24]:

Rating	**Description**
100	Fully active, normal
90	Minor restrictions with strenuous physical activity
80	Active, but gets tired quickly
70	Both greater restriction of, and less time spent in, active play
60	Up and around, but minimal active play; keeps busy with quieter activities
50	Lying around much of the day, but gets dressed; no active play; participates in all quiet play activities
40	Mostly in bed; participates in quiet activities
30	Stuck in bed; needs help even for quiet play
20	Often sleeping; play is entirely limited to very passive activities
10	Does not play or get out of bed
0	Unresponsive

V. Kurtzke Expanded Disability Status Scale (EDSS)

The EDSS is one of the most widely used assessment instruments in MS. It is a clinical rating scale ranging from 0 (normal neurological examination) to 10 (death due to MS) in half point increments. It is used in conjunction with the Kurtzke Functional System Scores, observation, information concerning gait and use of assistive devices in order to rate the EDSS. The guidelines recommend that patients with an EDSS of 2.0-5.5 could be considered for auto-HSCT, with 2.0 defined as minimal disability in one functional system (FS) score, and 5.5 defined as ambulatory without aid or rest for about 100 meters; disability severe enough to preclude full daily activities.

SUPPORTIVE LITERATURE

Blood Plasma Cancers

Acute Myeloid Leukemia

A meta-analysis published by Nathan et al (2004) compared survival outcomes for auto-HCT in CR1 with standard chemotherapy or no further treatment in AML patients ages 15 to 55 years. Two types of studies were eligible: (1) prospective cohort studies in which patients with an available sibling donor were offered allogeneic hematopoietic stem cell transplantation (allo-HCT) (biologic randomization) with random assignment of all others to auto-HCT or chemotherapy (or no further treatment); and (2) randomized trials that compared auto-HCT with chemotherapy in all patients. Among a total of 4058 patients included in 6 studies, 2989 (74%) achieved CR1; 1044 (26%) were randomized to HCT (n=524) or to chemotherapy (n=520). Of the 5 studies for which overall survival (OS) data were available, outcomes with auto-HCT were better in three, and outcomes with chemotherapy were better in two. None of the differences were statistically significant, nor was the pooled estimate (fixed-effects model survival probability ratio, 1.01; 95% CI, 0.89 to 1.15; p=.86). In all six studies, disease free survival (DFS) was numerically superior using auto-HCT compared with chemotherapy (or no further treatment), but only one reported a statistically significant DFS probability associated with auto-HCT. The pooled estimate for DFS showed a statistically significant probability in favor of auto-HCT at 48 months posttransplant (fixed-effects model survival probability ratio, 1.24; 95% CI, 1.06 to 1.44; p=.006). This review comprised studies performed between 1984 and 1995, during which transplant protocols and patient management evolved significantly, particularly compared with current care.

A second meta-analysis, published by Wang et al (2010), evaluated auto-HCT plus further chemotherapy or no further treatment for patients with AML in CR1. A total of nine randomized trials involving 1104 adults who underwent auto-HCT and 1118 patients who received additional chemotherapy or no additional treatment were identified. Analyses suggested that auto-HCT in CR1 is associated with a statistically significant reduction of relapse risk (relative risk, 0.56; 95% CI, 0.44 to 0.71; p=.001) and significant improvement in DFS (HR, 0.89; 95% CI, 0.80 to 0.98), but at the cost of an increased non-relapse mortality rate (relative risk, 1.90; 95% CI, 1.34 to 2.70; p=.23). There were more deaths during the first remission among patients assigned to auto-HCT than among the chemotherapy recipients or further untreated patients. As a consequence of the increased non-relapse mortality rate, no statistical difference in OS (HR, 1.05; 95% CI, 0.91 to 1.21) was associated with the use of auto-HCT, compared with further chemotherapy or no further therapy. These results are concordant with the earlier meta-analysis.

A prospective, randomized phase 3 trial by Vellenga et al (2011) compared auto-HCT with intensive consolidation chemotherapy among patients (range, 16 to 60 years) with newly diagnosed AML of similar risk profiles in CR1. After two cycles of intensive chemotherapy (etoposide and mitoxantrone), patients in CR1 who were not a candidate for allo-HCT were randomized to a third consolidation cycle of the same chemotherapy (n=259) or auto-HCT (n=258). The HCT group experienced an upward trend toward superior regression free survival (RFS) (38%) compared with the chemotherapy group at five years (29%; p=.065). The HCT patients also had a lower relapse rate at five years (58%)

compared with chemotherapy recipients (70%; p=.02). The OS did not differ between the HCT group (44%) and the chemotherapy group (41%; p=.86). Non-relapse mortality rates were higher in the auto-HCT group (4%) than in the chemotherapy consolidation group (1%; p=.02). Despite this difference in non-relapse mortality, the relative equality of OS rates was attributed by the investigators to a higher proportion of successful salvage treatments (second-line chemotherapy, autologous or allo-HCT) in the chemotherapy consolidation recipients that were not available to the auto-HCT patients. This large trial has shown an advantage for post-remission auto-HCT in reducing relapse, but similar OS rates secondary to better salvage of chemotherapy-consolidated patients.

Miyamoto et al (2018) reported results of a randomized, multicenter phase 3 trial conducted in 24 centers in Japan from 2003 to 2011 that compared auto-HCT versus HiDAC consolidation as post-remission therapy in AML. This trial enrolled 240 patients between 15 and 64 years of age with newly diagnosed favorable- and intermediate-risk AML and Eastern Cooperative Oncology Group (ECOG) performance status of <3; 87 of those who achieved CR1 were randomized to auto-HCT or HiDAC. The study was powered to include 122 patients with 5 years of accrual and 3 years of post-accrual follow-up to detect a difference in DFS at 3 years of 40% versus 65%. Approximately one-third of the patients had favorable risk AML, and the remaining two-thirds had intermediate-risk AML. The median age was 48 years. Median follow-up was approximately 4.5 to 5 years. Three-year DFS rate was 41% (95% CI, 27% to 55%) in the HiDAC group and 55% (95% CI, 38% to 68%) in the auto-HCT group (p=.25). Three-year OS was 77% (95% CI, 61% to 87%) versus 68% (95% CI, 52% to 80%) (p=.67). Cumulative incidence of relapse was 54% versus 41% (p=.22). There were no differences between the HiDAC and auto-HCT groups in the incidence of liver or renal dysfunction. The incidence of life-threatening infectious complications (p=.003) and mucositis/diarrhea (p=.002) was significantly higher in the auto-HCT group.

Multiple Myeloma

Chakraborty et al (2022) conducted a meta-analysis investigating the impact of high-dose therapy (HDT) consolidation on survival outcomes in patients with newly diagnosed multiple myeloma, focusing on differences between those with standard-risk and high-risk cytogenetics. Researchers reviewed randomized controlled trials from 2000 to 2021 comparing HDT to standard-dose therapy (SDT). Six trials were included for progression-free survival (PFS) analysis and four for OS, with follow-ups ranging from 3.1 to 7.8 years. The results showed that HDT significantly improved OS in high-risk patients (HR 0.66) compared to standard-risk patients (HR 0.90), with a statistically significant interaction (P = .03). For PFS, HDT also showed benefits in both groups, but the difference between them was not statistically significant (P = .25). Overall, the study concluded that the survival benefit of HDT is influenced by cytogenetic risk, supporting the use of upfront HDT consolidation particularly in high-risk patients.

POEMS Syndrome

For individuals who have POEMS syndrome (Polyneuropathy, Organomegaly, Endocrinopathy, Monoclonal gammopathy, and Skin abnormalities Syndrome) who receive HCT, the evidence includes retrospective cohort studies, case reports, and case series. Relevant outcomes are OS and treatment-related morbidity. No RCTs of HCT of any type have been performed in patients with POEMS

syndrome of any severity, nor is it likely such studies will be performed because of the rarity of this condition. Available case reports and series are subject to selection bias and are heterogeneous concerning treatment approaches and peritransplant support. However, for patients with disseminated POEMS syndrome, a chain of evidence and contextual factors related to the disease and multiple myeloma would suggest improvement in health outcomes with auto-HCT. The evidence is sufficient to determine that the technology results in an improvement in the net health outcome.

Hodgkin Lymphoma (HL)

A systematic review and meta-analysis of the available RCTs on HCT for patients with relapsed or refractory HL were published by Rancea et al (2014). Reviewers included three RCTs, 2 (1993, 2002) of which compared HDC plus auto-HCT with conventional treatment. Both trials were judged to be at moderate risk of bias using the Cochrane criteria. Combined analysis for the outcome of OS demonstrated a hazard ratio of 0.67 for patients treated with auto-HCT, which was not statistically significant (95% CI, 0.41 to 1.07). For the outcome of progression-free survival (PFS), there was a significant improvement for auto-HCT treatment, with a hazard ratio of 0.55 (95% CI, 0.35 to 0.86).

A retrospective observational cohort study by Merryman et al (2021) evaluated auto-HCT after anti-programmed death-1 (PD-1) therapy for patients with relapsed or refractory HL. A total of seventy-eight patients who were identified underwent auto-HCT as a third-line (or later) treatment; 74% of patients underwent auto-HCT after anti-PD-1 treatment and 26% of patients received anti-PD-1 treatment along with additional therapy prior to auto-HCT. The 18-month PFS and OS after auto-HCT were 81% (95% CI, 69 to 89) and 96% (95% CI, 87 to 99), respectively. Favorable outcomes were reported for patients who had received greater than four systemic therapies before auto-HCT (18-month PFS, 73%), who were refractory to two consecutive therapies immediately prior to anti-PD-1 treatment (18-month PFS, 78%), and who had positive pre-HCT positron emission tomography (PET) (18-month PFS, 75%); patients who were non-responders to anti-PD-1 treatment had inferior outcomes (18-month PFS, 51%).

Diffuse Large B-Cell Lymphoma (DLBCL)

Results of a phase 3 multicenter randomized trial, Chemoradiotherapy and Peripheral Stem Cell Transplantation Compared with Combination Chemotherapy in Treating Patients with Non-Hodgkin's Lymphoma (SWOG-9704) of auto-HCT as consolidation for aggressive (high-intermediate or high-risk) DLBCL were published in 2013 (Stiff et al). In this trial, 253 patients received five cycles of induction chemotherapy (CHOP with [n=156 (47%)] or without rituximab). Those who had at least a PR to five cycles of induction therapy were randomized to three additional cycles of CHOP (n=128) or one additional cycle of CHOP followed by auto-HCT (n=125). The primary efficacy endpoints of the trial were 2-year PFS and OS. Two-year PFS rates were 69% and 55% in the HCT and control group, respectively (HR control vs. HCT, 1.72; 95% CI, 1.18 to 2.51; p=.005). The 2-year OS rates in the HCT and control group were 74% and 71%, respectively (HR, 1.26; 95% CI, 0.82 to 1.94; p=.30). Unplanned exploratory analyses showed a differential treatment effect by disease risk level. Among high-risk patients, the 2-year OS rate was 82% in the HCT group and 64% in the control group (p=.01). The main results of this trial are consistent with earlier study results in not discerning a significant effect of early auto-HCT on OS among a group of patients with high-, intermediate-, and

high-risk diffuse B-cell NHL. However, the survival curve appeared to plateau among the high-risk HCT patients out to 10 years after study registration. Although this evidence was from exploratory subset analysis, it further supports the efficacy of this approach in such cases compared with nontransplant strategies.

The pivotal trial that established the superiority of auto-HCT for relapsed DLBCL is the Autologous Bone Marrow Transplantation as Compared with Salvage Chemotherapy in Relapses of Chemotherapy-Sensitive Non-Hodgkin's Lymphoma (PARMA) (Philip et al 1995), a prospective randomized study in which 215 patients with chemosensitive disease in first or second relapse of aggressive lymphoma were given two courses of conventional chemotherapy. A total of 109 patients responded and were randomized to four courses of chemotherapy plus radiotherapy (n=54) or radiotherapy plus intensive chemotherapy and auto-HCT (n=55). The groups did not differ in baseline characteristics. Median follow-up was 63 months. The response rate was 84% in the HCT group and 44% in the nontransplant group. The event free survival (EFS) rate for the transplant group was 46% and 12% in the nontransplant group (p=.001); the OS rate was 53% in the transplant group and 32% in the nontransplant group (p=.038).

Follicular Lymphoma (FL)

Follicular lymphoma is the most common indolent Non-Hodgkin Lymphoma (NHL) (70% to 80% of cases), and often the terms indolent lymphoma and FL are used synonymously. Also included in the indolent NHL are small lymphocytic lymphoma/chronic lymphocytic lymphoma, lymphoplasmacytic lymphoma, marginal zone lymphomas, and cutaneous T-cell lymphoma.

Schaaf et al (2012) performed a systematic review of RCTs comparing auto-HCT with chemotherapy or immunochemotherapy in patients with previously untreated or relapsed FL concerning OS, PFS, treatment-related mortality, adverse events, and secondary malignancies. Five RCTs involving 1093 patients were included, with four trials in previously untreated patients and one in relapsed patients. The quality of the five trials was judged to be moderate. There was a statistically significant increase in PFS in previously untreated FL patients in the HCT arm (hazard ratio [HR], 0.42; 95% confidence interval [CI], 0.33 to 0.54; p<.001). However, there was no statistically significant OS advantage (HR, 0.97; 95% CI, 0.76 to 1.24; p=.81). In the four trials in previously untreated patients, there were no statistically significant differences between HCT and the control arm in terms of treatment-related mortality (relative risk [RR], 1.28; 95% CI, 0.25 to 6.61; p=.77), secondary acute myeloid leukemia/myelodysplastic syndromes (RR, 2.87; 95% CI, 0.7 to 11.75; p=.14), or solid cancers (RR, 1.20; 95% CI, 0.25 to 5.77; p=.82). Adverse events were rarely reported but were more frequent in patients who underwent HCT. For patients with relapsed FL, there was some evidence from one trial with 70 patients that HCT was advantageous regarding PFS (HR, 0.30; 95% CI, 0.15 to 0.61) and OS (HR, 0.40; 95% CI, 0.18 to 0.89). No results were reported from this trial for treatment-related mortality, adverse events, or secondary cancers.

In most patients with FL relapse, and with relapsed disease, a cure is unlikely, with a median survival of 4.5 years after recurrence. In the European CUP trial (Schouten et al 2004), 89 patients with relapsed, non-transformed FL with PR or CR after standard induction chemotherapy were randomized to one of three arms: three additional cycles of conventional chemotherapy (n=24), high-dose

chemotherapy and unpurged auto-HCT (n=33), or high-dose chemotherapy with purged auto-HCT (n=32). The OS rates at 4 years for chemotherapy versus unpurged versus purged arms were 46%, 71%, and 77%, respectively. Two-year PFS rates were 26%, 58%, and 55%, respectively. No difference was found between the auto-HCT arms. Although several studies have consistently shown improved DFS with auto-HCT for relapsed FL, this study was the first to show a difference in OS benefit.

Mantle Cell Lymphoma (MCL)

Zoellner et al (2021) conducted a post-hoc analysis of an open-label, multicenter, randomized phase 3 trial on previously untreated MCL patients. A total of 269 patients were randomized to receive myeloablative radiochemotherapy followed by auto-HCT (n=134) or interferon alfa maintenance after completion of a CHOP-like induction therapy (n=135) with or without rituximab. The median follow-up period was 14 years, with the intention-to-treat population consisting of 174 patients (93 in the auto-HCT group and 81 in the interferon alfa maintenance group) who responded to induction therapy. The median PFS in the auto-HCT group was 3.3 years (95% CI, 2.5 to 4.3 years) compared to 1.5 years (95% CI, 1.2 to 2.0 years) in the interferon alfa group (log-rank p<.0001; adjusted HR, 0.5 [95% CI, 0.36-0.69]). The median OS in the auto-HCT group was 7.5 years (95% CI, 5.7 to 12.0 years) and 4.8 years (95% CI, 4.0 to 6.6 years) in the interferon alfa group (log-rank p=.019; adjusted HR, 0.66 [95% CI, 0.46-0.95]). For patients treated with a rituximab-containing induction regimen, neither PFS nor OS was significantly different between the 2 groups.

Metzner et al (2023) reported long-term outcomes for a series of 65 individuals with MCL who received auto-HCT. 54 (83%) received first-line auto-HCT, 10 (15%) received second-line auto-HCT. The 10-year OS and PFS after first-line HCT were 64% and 52%, respectively. 10-year OS and PFS after second-line HCT was 50% and 20%. Treatment-related mortality 3 months after HCT was 1.5%. At the time of publication, 26 of the individuals who received first-line HCT remained in complete remission up to 19 years following HCT.

Dreyling et al (2024) conducted an RCT evaluating the impact of adding ibrutinib to standard immunochemotherapy in younger patients (aged ≤65 years) with MCL. The TRIANGLE study assessed whether ibrutinib-enhanced regimens could improve clinical outcomes compared to standard treatment involving auto-HCT or to an ibrutinib-containing regimen without auto-HCT. The trial included 870 patients with untreated stage II to IV MCL who were randomized 1:1:1 to a control group receiving alternative R-CHOP and rituximab, dexamethasone, cytosine-arabinoside, and platinum (R-DHAP) followed by auto-HCT (group A), an experimental group receiving the same regimen with added ibrutinib during induction and as maintenance therapy post- auto-HCT (group A+I), or another experimental group receiving ibrutinib without auto-HCT (group I). The primary outcome was failure-free survival (FFS). After a median follow-up of 31 months, group A+I demonstrated superior FFS compared to group A, with 3-year FFS rates of 88% vs 72%, respectively (HR, 0.52; 98.3% CI, 0 to 0.86; p=.0008). However, the superiority of group A over group I was not shown, with 3-year FFS rates of 72% vs 86%, respectively (HR, 1.77; 98.3% CI, 0 to 3.76; p=.9979). The comparison between groups A+I and I is ongoing. During maintenance or follow-up, grade 3 to 5 hematological adverse events occurred in 50% of patients in group A+I, 28% in group I, and 21% in group A. Infections were reported in 25% of patients in group A+I, 19% in group I,

and 13% in group A. The results of this study demonstrate that Auto-HSCT is no longer clearly superior to ibrutinib-containing immunochemotherapy without ASCT in first complete remission.

Peripheral T-Cell Lymphoma (PTCL)

Schmitz et al (2021) conducted a randomized, prospective phase 3 trial of autologous versus allo-HCT as part of first-line therapy in patients with PTCL. There were 104 patients enrolled, age 18 to 60 years, who were randomized to four cycles of CHOP without etoposide (CHOEP) and 1 cycle of DHAP followed by high-dose therapy and auto-HCT (n=54) or myeloablative conditioning and allo-HCT (n=49). A few study patients were unable to proceed with transplantation due to disease progression, toxicity, or other reasons, so the final patient population consisted of 41 patients who underwent auto-HCT and 26 patients who underwent allo-HCT. The median follow-up period was 42 months and the 3-year EFS was 38% (95% CI, 25% to 52%) in the auto-HCT group versus 43% (95% CI, 29% to 57%) in the allo-HCT group. The 3-year OS was 70% (95% CI, 57% to 82 %) in the auto-HCT group versus 57% (95% CI, 43% to 71%) in the allo-HCT group.

Girard et al (2024) published a meta-analysis including 17 studies (N=1798) that compared upfront auto-HCT in patients with PTCL achieving first CR post-chemotherapy, with chemotherapy treatment alone. Histological subtypes included in the studies were heterogeneous, though the majority of patients had nodal PTCL. Results demonstrated that among transplant-eligible patients in CR after chemotherapy, auto-HCT provided significant benefits in both PFS (9 studies; HR, 0.61; 95% CI, 0.47 to 0.81) and OS (3 studies; HR, 0.59; 95% CI, 0.36 to 0.95). Subgroup analysis showed that angioimmunoblastic T-cell lymphoma patients in CR derived a significant PFS benefit from auto-HCT (3 studies; HR, 0.43; 95% CI, 0.20 to 0.94), though no significant OS advantage was noted.

Solid Tumors

Matthay et al (1999) randomized 129 children with high-risk neuroblastoma to a combination of myeloablative chemotherapy, total body irradiation, and transplantation of autologous bone marrow and compared their outcomes with those of 150 children randomized to intensive nonmyeloablative chemotherapy; both groups underwent a second randomization to subsequent 13-cis-retinoic acid (cis-RA) or no further therapy. The 3-year event free survival (EFS) rate among patients assigned to transplantation was 43% and 27% among those assigned to continuation chemotherapy (p=.027). However, OS rates for both groups did not differ significantly, with 3-year estimates of 43% or 44% for those assigned to transplant and continued chemotherapy, respectively (p=.87). Long-term results from this trial were reported in 2009 after a median follow-up of 7.7 years (range, 130 days to 12.8 years). The 5-year EFS rate for patients who underwent auto-HCT was 30% and 19% for those who underwent nonmyeloablative chemotherapy (p=.04). Five-year OS rates from the second randomization of patients who underwent both random assignments were 59% for autologous transplant/cis-RA, 41% for auto-HCT/no cis-RA, and, for nonmyeloablative chemotherapy, 38% and 36% with and without cis-RA. Authors concluded that myeloablative chemotherapy and auto-HCT resulted in significantly better 5-year EFS and OS rates.

A systematic review by Żebrowska et al (2024) evaluated the survival benefits of myeloablative therapy (MAT) combined with auto-HCT in high-risk neuroblastoma. Analysis of RCTs revealed significant improvements in event-free survival (HR, 0.78; 95% CI, 0.67 to 0.91; p=.001) and a trend

toward OS benefit (HR, 0.86; 95% CI, 0.73 to 1.00; p=.05) with MAT+ auto-HCT compared to conventional chemotherapy or no further treatment. Tandem MAT+ auto-HCT demonstrated superior event-free survival and OS compared to single auto-HCT, particularly when followed by anti-disialoganglioside 2 immunotherapies. Limited evidence suggested an increased risk of relapse when MAT+ auto-HCT was omitted prior to anti-GD2 therapy, while MAT+ auto-HCT also appeared to improve OS in relapsed patients, though data were sparse.

Non- Malignant Conditions

Multiple Sclerosis

Ruiz-Argüelles et al (2019) conducted a single-center, prospective study of 617 consecutive patients with multiple sclerosis (MS) referred for autologous hematopoietic stem cell transplantation (HSCT) between June 2015 and March 2019. The goal was to assess the safety and efficacy of the "Mexican method," which uses a conditioning regimen based on cyclophosphamide and rituximab. Eligible patients included those with relapsing-remitting MS (RRMS), secondary progressive MS (SPMS), or primary progressive MS (PPMS), provided they had a Karnofsky performance status above 70% and an Expanded Disability Status Scale (EDSS) score of 8 or lower within two weeks prior to transplant. All patients underwent a washout period of at least three months from other immunosuppressive agents. Follow-up ranged from 3 to 42 months (median: 12 months). Primary endpoints were recovery of granulocyte and platelet counts and transplant-related mortality (TRM). Secondary endpoints included overall survival (OS) and clinical response, defined as improvement or stabilization of the self-reported EDSS score. Of the 617 participants, 216 were male (35%) and 401 female (65%), with a median age of 46 years (range: 18–73). MS subtypes included 259 RRMS (42%), 228 SPMS (37%), and 130 PPMS (21%). The median EDSS score was 5.5 (range: 0–8; interquartile range: 4–6.5). All transplants were performed on an outpatient basis; 32 patients required brief hospitalization (15 for neutropenic fever, six for MS flare, four for pneumothorax requiring chest tube). Eleven patients required red blood cell transfusions, and six needed platelet transfusions. Thirty-month survival was 100%. At 12 months, 78% of patients reported improvement or stabilization of EDSS scores, with the best outcomes in RRMS (83%). Disability progression-free survival was 82% overall. A limitation of the study was that MRI was not systematically used to confirm self-reported improvements. The authors concluded that HSCT is safe and effective, particularly for RRMS.

Nabizadeh et al (2022) reviewed 50 studies involving 4,831 patients to assess the safety and effectiveness of autologous hematopoietic stem cell transplantation (AHSCT) for multiple sclerosis (MS). The analysis found that AHSCT significantly improved disability scores and reduced relapse rates compared to pre-treatment. After transplantation, 73% of patients remained progression-free, 81% were relapse-free, and 63% had no disease-related events. MRI activity-free survival was 89%, with only 8% developing new lesions. Additionally, 68% achieved no evidence of disease activity (NEDA), and overall survival was high at 94%. However, transplant-related mortality was 4%, indicating some risk despite the generally favorable outcomes.

Scleroderma

An open-label, randomized, controlled phase 2 trial (Trial of High Dose Cyclophosphamide and Rabbit Antithymocyte Globulin [rATG] With Hematopoietic Stem Cell Support in Patients with Systemic Scleroderma: A Randomized Trial [ASSIST]; Burt et al 2011) evaluated the safety and efficacy of autologous nonmyeloablative HCT compared with standard cyclophosphamide therapy. The primary outcome was improvement at 12 months, defined as either a decrease in modified Rodnan skin score (mRSS) of at least 25% for patients with an initial mRSS >14, or an increase in forced vital capacity (FVC) of more than 10%. Patients in the control group who experienced disease progression (>25% increase in mRSS or >10% decrease in FVC) despite cyclophosphamide could switch to HCT after 12 months. Patients assigned to HCT (n=10) improved at or before the 12-month follow-up, compared with none of the nine patients assigned to cyclophosphamide (p<.001). Treatment failure (disease progression without improvement) occurred in eight of nine controls but in none of the HCT patients (p<.001). After a mean follow-up of 2.6 years, all but two HCT patients had sustained improvement in mRSS and FVC, with the longest follow-up reaching 60 months. Seven patients from the cyclophosphamide group switched to HCT at a mean of 14 months after enrollment and all improved without complications. Among four of these patients followed for at least one year, mRSS decreased from a mean of 27 (SD=15.5) to 15 (SD=7.4), FVC increased from 65% (SD=20.6%) to 76% (SD=26.5%), and total lung capacity rose from 81% (SD=14.0%) to 88% (SD=13.9%). Data for 11 patients with two years of follow-up after HCT suggested that improvements in mRSS (p<.001) and FVC (p<.03) persisted.

Sullivan et al (2018) conducted an RCT comparing auto-HCT with cyclophosphamide for the treatment of scleroderma (SCOT – A Randomized, Open-Label, Phase II Multicenter Study of High-Dose Immunosuppressive Therapy Using Total Body Irradiation, Cyclophosphamide, ATGAM, and Autologous Transplantation with Auto-CD34+HPC Versus Intravenous Pulse Cyclophosphamide for the Treatment of Severe Systemic Sclerosis [SCSSc-01]). The trial was originally designed for 226 patients, but due to low enrollment, 75 patients participated. Of the 36 patients randomized to HCT, 27 completed the trial per protocol (3 died and 6 withdrew early). Of the 39 patients randomized to cyclophosphamide alone, 19 completed per protocol (11 died and 9 withdrew early). The primary outcome was a global rank composite score, which does not measure disease activity directly but compares outcomes in pairs based on death, EFS, FVC, Disability Index of the Health Assessment Questionnaire, and mRSS. At 4 and 4.5 years of follow-up, more pairwise comparisons favored HCT over cyclophosphamide. Disease progression events were significantly higher in the cyclophosphamide group for initiating disease-modifying antirheumatic drugs, congestive heart failure requiring treatment, and pulmonary arterial hypertension. Events such as arrhythmia, pericardial effusion, renal crisis, and myositis did not differ significantly between groups.

PROFESSIONAL GUIDELINE(S)

In 2019, Cohen and colleagues published a position statement from the American Society for Blood and Marrow Transplantation (ASBMT) addressing the use of auto-HCT in treatment-refractory relapsing MS. The position statement is as follows:

"The ASBMT Task Force recommends revising the recommended indication for AHCT in MS to "standard of care, clinical evidence available", for patients with relapsing forms of MS (RRMS or

progressive MS with superimposed activity) who have prognostic factors that indicate a high risk of future disability, including ongoing clinical relapse or MRI lesion activity despite treatment with available DMTs, especially if disease activity continues despite treatment with high-efficacy DMTs and/or worsening disability."

In 2020, the American Society of Transplantation and Cellular Therapy (ASTCT) convened a guideline committee to make recommendations for the use of hematopoietic cell transplantation and immune effector cell therapy. Indications were categorized as (1) Standard of care, where indication is well defined and supported by evidence; (2) Standard of care, clinical evidence available, where large clinical trials and observational studies are not available but have shown to be effective therapy; (3) Standard of care, rare indication, for rare diseases where demonstrated effectiveness exists but large clinical trials and observational studies are not feasible; (4) Developmental, for diseases where preclinical or early-phase clinical studies show promising results, and (5) not generally recommended, where available evidence does not support the routine use of hematopoietic stem cell transplantation. The following indications have auto-HCT categorized as standard of care for pediatric patients under the age of 18:

- Hodgkin lymphoma, first relapse, sensitive;
- Ewing sarcoma, high risk or relapse;
- Neuroblastoma, high risk or relapse.

The following indications have auto-HCT categorized as standard of care for adult patients:

- Hodgkin lymphoma, first relapse (sensitive);
- Ewing sarcoma, high risk or relapse;
- Neuroblastoma, high risk or relapse;
- Acute promyelocytic leukemia, CR2, molecular remission;
- Myeloma, initial response, or sensitive relapse;
- Amyloid light-chain amyloidosis;
- Hodgkin lymphoma, primary refractory (sensitive), first relapse (sensitive), or second or greater relapse;
- Diffuse Large B cell lymphoma, primary refractory (sensitive); first relapse (sensitive), or second or greater relapse;
- Follicular lymphoma, primary refractory (sensitive), second or greater relapse, or transformation to high grade lymphoma;
- Mantle cell lymphoma, CR1, first partial remission, primary refractory (sensitive) first relapse (sensitive), or second or greater relapse;
- T cell lymphoma, CR1/first partial remission, primary refractory (sensitive), first relapse (sensitive);

- Lymphoplasmocytic lymphoma/Waldenstrom macroglobulinemia, first or greater relapse (sensitive);
- Chronic lymphocytic leukemia, transformation to high-grade lymphoma;
- Germ cell tumor, relapse, or refractory; and
- Systemic sclerosis.

In 2021, the ASTCT, Center of International Blood and Marrow Transplant Research (CIBMTR), and the European Society for Blood and Marrow Transplantation (EBMT) formulated consensus recommendations regarding auto-HCT, allo-HCT, and chimeric antigen receptor (CAR) T-cell therapy for patients with MCL (Munshi et al). The panel of experts, consisting of physicians and investigators, recommended the use of auto-HCT as consolidation therapy in newly diagnosed MCL patients (without TP53 mutation or bi-allelic deletion) who are in complete or partial remission after first-line therapies.

The ASTCT Committee on Practice Guidelines published guidance on transplantation and cellular therapies in DLBCL in 2023 (Epperla et al). The committee made the following recommendations:

- "The panel does not recommend auto-HCT in DLBCL (regardless of IPI score) as consolidation in complete remission after first-line (R-CHOP or similar) therapy." (Grading: A)
- "Autologous HCT may be considered for eligible patients with DLBCL with secondary CNS involvement at diagnosis achieving complete remission and with undetectable CNS disease after first-line therapy." (Grading: C)
- "The panel recommends consolidation with autologous HCT for eligible primary CNS lymphoma patients in CR1."(Grading: A)
- "In DLBCL patients with early relapse who achieve a complete remission with salvage therapy, the panel considers autologous HCT an acceptable consolidation therapy in eligible patients."(Grading: B)
- "In DLBCL patients with early relapse who achieve a partial remission with salvage therapy, the panel considers autologous HCT an acceptable consolidation therapy in eligible patients." (Grading: B)
- "In DLBCL patients with late relapse, the panel recommends autologous HCT consolidation therapy in eligible patients who have achieved a complete or partial remission after second-line therapies." (Grading: A)
- "The panel recommends allogeneic HCT in eligible DLBCL patients relapsing/progressing after CAR-T therapy if they achieve a complete or partial remission with subsequent antilymphoma therapies." (Grading: C)
- "The panel recommends allogeneic HCT in eligible relapsed or refractory DLBCL patients after autologous HCT failure in regions without access to CAR-T therapy, and in those with CAR T cell manufacturing failure, ideally after achieving a complete or partial remission with subsequent antilymphoma therapies." (Grading: C)

Grading of recommendations:

- A- There is good research-based evidence to support the recommendation;
- B- There is fair research-based evidence to support the recommendation;
- C- The recommendation is based on expert opinion and panel consensus;
- X- There is evidence of harm from this intervention.

The National Comprehensive Cancer Network (NCCN) V.2.2025 clinical practice guidelines for pediatric aggressive mature B-cell lymphomas recommends HSCT for the treatment of relapsed or refractory disease, and that "the decision regarding the type of HSCT [autologous versus allogeneic] should be based upon donor availability and physician preference." However, it is recommended that patients with a complete response to second-line therapy (e.g., rituximab, dexamethasone, cytarabine, and cisplatin) are better suited for an autologous HSCT.

In 2024, ASTCT and EBMT formulated consensus recommendations for HCT and cellular therapies in follicular lymphoma (Iqbal et al). The following consensus statements regarding auto-HCT were made:

"Front-line setting (i.e., HCT following first-line chemotherapy):

- The panel does not recommend autologous or allogeneic HCT as consolidation therapy in eligible follicular lymphoma patients in complete or partial remission after first-line therapies."

"Early first relapse/progression (i.e., first relapse occurred on or within 24 months from receiving front-line chemoimmunotherapy (post-operative day [POD] 24) and without evidence of histological transformation):

- The panel recommends autologous HCT as an option for consolidation therapy in eligible, relapsed POD24 follicular lymphoma patients who have achieved complete or partial remission after second-line therapies.
- The panel does not recommend autologous HCT as consolidation therapy in eligible, relapsed follicular lymphoma patients who do not achieve complete or partial remission after second or subsequent line therapies.

"Late first relapse, second relapse, and beyond settings:

- The panel does not recommend autologous HCT as consolidation therapy in eligible, relapsed follicular lymphoma patients who did not achieve complete or partial remission after second or subsequent line therapies.
- The panel does not recommend autologous HCT as consolidation therapy in eligible, relapsed follicular lymphoma patients who have relapsed after CAR T-cell therapy and did not achieve complete or partial remission to the most recent anti-lymphoma treatment."

In 2023, Fraint and colleagues published a report from the ASTCT Committee on practice guidelines for the evaluation of children with malignancies for blood and marrow transplantation. ASTCT states, "Children with malignancy who require HCT for cure have a unique set of psychosocial needs,

physical comorbidities, and disease risk features that differentiate them from adults. Given the inability for some of the important pre-HCT risk indices developed for adults to be applied to children, a specialized approach is needed, ideally with harmonization among centers." Although rigorous data on physiologic differences and randomized trials on management are lacking for children, the recommendations provided are meant to serve as a guide for pre-HCT preparations.

REGULATORY STATUS

The U.S. Food and Drug Administration (FDA) regulates vaccines, blood and blood products, and biologics via the Center for Biologics Evaluation and Research (CBER) which ensures the safety, efficacy, and quality of these products. Refer to the FDA vaccines/blood/biologics website. Available from: Vaccines, Blood & Biologics | FDA [accessed 2025 Nov 24]

The FDA maintains information for consumers and health professionals on vaccine, blood and biologics warnings and other safety information. Available from: Recalls (Biologics) | FDA [accessed 2025 Nov 24]

HCPCS Codes

Code	Description
S2150	Bone marrow or blood-derived stem cells (peripheral or umbilical), allogeneic or autologous, harvesting, transplantation, and related complications; including: pheresis and cell preparation/storage; marrow ablative therapy; drugs, supplies, hospitalization with outpatient follow-up; medical/surgical, diagnostic, emergency, and rehabilitative services; and the number of days of pre and post-transplant care in the global definition

ICD10 Codes

Code	Description
C26.0-C26.9	Malignant neoplasm of other and ill-defined digestive organs (code range)
C33	Malignant neoplasm of trachea
C34.00-C34.92	Malignant neoplasm of bronchus and lung (code range)
C38.1-C38.8	Malignant neoplasm of heart, mediastinum and pleura (code range)
C47.0-C47.9	Malignant neoplasm of peripheral nerves and autonomic nervous system (code range)
C48.0	Malignant neoplasm of retroperitoneum
C49.0-C49.9	Malignant neoplasm of other connective and soft tissue (code range)
C50.011-C50.919	Malignant neoplasm of breast (code range)
C62.00-C62.92	Malignant neoplasm of testis (code range)
C71.0-C71.9	Malignant neoplasm of brain (code range)
C81.00-C81.99	Hodgkin lymphoma (code range)
C82.00-C82.99	Follicular lymphoma (code range)
C83.00-C83.09	Non-follicular lymphoma (code range)
C83.10-C83.19	Mantle cell lymphoma (code range)
C83.30-C83.39	Diffuse large B-cell lymphoma (code range)

Code	Description
C83.50-C83.59	Lymphoblastic (diffuse) lymphoma (code range)
C83.70-C83.79	Burkitt lymphoma (code range)
C83.80-C83.99	Other non-follicular lymphoma (code range)
C84.60-C84.79	Anaplastic large cell lymphoma, ALK-positive or ALK-negative (code range)
C86.5	Angioimmunoblastic T-cell lymphoma
C86.6	Primary cutaneous CD30-positive T-cell proliferations
C88.2-C88.9	Malignant immunoproliferative diseases and certain other B-cell lymphomas (code range)
C90.00-C90.32	Multiple myeloma and malignant plasma cell neoplasms (code range)
C91.10-C91.12	Chronic lymphocytic leukemia of B-cell type (code range)
E85.0-E85.9	Amyloidosis (code range)
G35	Multiple sclerosis
M05.00-M05.09	Felty's syndrome (code range)
M05.20-M05.29	Rheumatoid vasculitis with rheumatoid arthritis (code range)
M05.30-M05.39	Rheumatoid heart disease with rheumatoid arthritis (code range)
M05.40-M05.59	Rheumatoid myopathy with rheumatoid arthritis (code range)
M05.60-M06.09	Rheumatoid arthritis with involvement of other organs and systems (code range)
M06.1	Adult-onset Still's disease
M06.4	Inflammatory polyarthropathy
M06.80-M06.9	Other specified rheumatoid arthritis (code range)

Code	Description
M08.00-M08.99	Juvenile arthritis (code range)
M12.00-M12.09	Other and unspecified arthropathy (code range)
M32.0-M32.9	Systemic lupus erythematosus (SLE) (code range)
M34.0-M34.9	Systemic sclerosis [scleroderma] (code range)

MEDICAL POLICY

Medical Policy Title	**Balloon Dilation of the Eustachian Tube (BDET)**
Policy Number	**7.01.101**
Current Effective Date	**January 1, 2026**
Next Review Date	**July 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Balloon dilation of the Eustachian tubes (BDET), unilateral or bilateral, is **medically appropriate** for the treatment of chronic obstructive Eustachian tube dysfunction (ETD) when **ALL** the following **criteria** are met:

   A. Age 18 years or older;

   B. Comprehensive diagnostic evaluation documents **all** of the following:

      1. abnormal tympanogram (Type B or C);
      2. abnormal tympanic membrane on examination (e.g., retracted membrane, effusion, or perforation); **and**
      3. other causes of aural fullness have been ruled out (e.g., temporomandibular joint disorders, extrinsic obstruction of the Eustachian tube, superior semicircular canal dehiscence, and endolymphatic hydrops);

   C. Symptoms of chronic obstructive ETD including **all** of the following:

      1. aural fullness and aural pressure;
      2. hearing loss or otalgia (earache/pain); **and**
      3. symptoms lasting (3) months or longer that are continuous and not episodic (e.g., symptoms occur only in response to barochallenge such as pressure changes while flying);

   D. Absence of any contraindication, including but not limited to:

      1. patulous ETD;
      2. dehiscence of carotid artery canal;

   E. No treatment history of prior BDET in the same ear for which the surgery is proposed;

   F. Treatment history includes the following, if applicable:

      1. failure to respond to appropriate medical management of coexisting conditions (e.g., allergic rhinitis, rhinosinusitis, and laryngopharyngeal reflux);

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

2. symptoms of obstructive ETD must have improved following myringotomy with tympanostomy tube placement (trial is not required for BDET).

II. BDET, unilateral or bilateral, is **investigational** for **ALL** other indications, including but not limited to:

A. As a repeat procedure;

B. Performed concurrent with tympanoplasty (ear drum repair) or other middle ear surgery (e.g., mastoidectomy);

C. Aural fullness but normal examination and tympanogram;

D. Transtympanic BDET;

E. Age 17 years and younger;

F. Extrinsic cause of ETD (e.g., but not limited to enlarged adenoid pads, history of radiation therapy to the nasopharynx, craniofacial syndrome [e.g., cleft palate spectrum], nasopharyngeal or skull base neoplasm, neoplasms causing extrinsic obstruction of the Eustachian tube).

POLICY GUIDELINE(S)

I. Comprehensive diagnostic evaluation ensures proper patient selection, which may result in successful outcomes of BDET in patients with true primary obstructive ETD. Essential assessments include a history and physical exam, otoscopy, nasal endoscopy, audiometry, and tympanometry. All assessments are inadequate to secure a diagnosis when relied upon in isolation (Tucci et al 2019).

II. Tympanometry measures the mobility of the tympanic membrane and graphically displays results in tympanograms. Tympanograms are classified by the height and location of the tympanometric peak:

A. Type A indicates normal middle ear and Eustachian tube function;

B. Type B indicates poor tympanic membrane mobility ("flat" tympanogram);

C. Type C indicates the presence of negative middle ear pressure.

III. Failure to relieve symptoms despite a functioning myringotomy or tympanostomy tube suggests a diagnosis other than obstructive ETD (e.g., patulous ETD).

IV. Individuals undergoing BDET concurrent with sinus ostial dilation should meet the same diagnostic criteria for BDET as those undergoing BDET alone. Individuals with a middle ear effusion at the time of BDET may benefit from concurrent myringotomy with or without

tympanostomy tube placement.

BDET can only be performed with a balloon dilation device/system that is approved by the U.S. Food and Drug Administration (FDA).

DESCRIPTION

The Eustachian tube (ET) is a fibrocartilaginous duct connecting the nasopharynx to the middle ear space. In adults, the ET is approximately 36 millimeters (mm) in length. It functions primarily to equalize air pressure between the middle ear and atmosphere, crucial to the proper working of the eardrum. The ET opens during yawning, swallowing, and sneezing which aids in equalized air pressure, clearing secretions, and protects the middle ear from infection and nasopharyngeal contents.

Eustachian tube dysfunction (ETD) is a broad diagnostic category that involves the inability of the ET to open and close appropriately. Common ET disorders include:

- Patulous ETD: the functional valve of the ET is pathologically patent, creating an abnormally persistent state of pressure equalization between the middle ear and nasopharynx. Diagnosis of patulous ETD is suggested by symptoms of autophony of voice, audible respirations.
- Obstructive ETD: patency of the ET is decreased by a functional or anatomical obstruction.
- Baro-challenge-induced ETD: failure of the ET to adequately open and regulate middle-ear pressure during ambient pressure changes, although ET function may be normal in normobaric situations.

Medical management of obstructive ETD is directed by the underlying etiology. Decongestants and antihistamines can be used for rhinosinusitis to relieve inflammation and secretions. Nasal steroid sprays can also be used to aid in the relief of inflammation. The American Academy of Otolaryngology- Head and Neck Surgery (AAO-HNS) clinical consensus statement supports that there is no standard medical therapy for primary obstructive ETD, therefore, in the absence of extrinsic causes, there is no absolute role for a treatment trial of topical or systemic medical therapy in primary OETD (Tucci et al 2019). Patients who do not find relief with medical management may be treated with surgery.

Available surgical interventions include myringotomy with tympanostomy tube placement, in which a small incision is made to the tympanic membrane and a small tube is placed, to allow for drainage of secretions. These procedures create an alternative route for ventilation of the middle ear space but do not address the functional problem at the Eustachian tube. Tympanostomy tube placement may be a repeat procedure for the life of the patient, and the risk of complications from tympanostomy tubes increases with increasing numbers of tube placements and duration of tube placement.

Balloon dilation of the Eustachian tube (BDET) is novel, minimally invasive tuboplasty procedure intended to improve the patency of the cartilaginous Eustachian tube and ease the symptoms of chronic ETD by expanding the Eustachian tube. During this procedure, a saline-filled balloon catheter is introduced into the Eustachian tube trans-nasally using a minimally invasive endoscopic method. Once the balloon is placed, it is inflated. Pressure is maintained for approximately two minutes,

followed by deflation and removal. BDET allows for the drainage of secretions and equalization of pressure across the tympanic membrane, providing relief for those suffering from ETD.

This transnasal procedure can be performed unilaterally or bilaterally and done as a stand-alone procedure or in conjunction with other procedures such as adenoidectomy, intranasal surgery (e.g., septoplasty, turbinate procedures, or sinus surgery), surgery for obstructive sleep apnea or sleep disturbed breathing, and myringotomy with or without tympanostomy tube placement.

Transtympanic approach to accessing the ET is a proposed technique to overcome limitation of the transnasal approach to perform BDET. There is limited and conflicting evidence to support its use.

SUPPORTIVE LITERATURE

For adults with chronic obstruction Eustachian tube dysfunction (ETD) who have not responded to medical management (if applicable) and who undergo balloon dilation of the Eustachian tube (BDET), the evidence is sufficient to conclude that this technology leads to an improvement in net health outcomes. However, there is a lack of published evidence supporting the use of BDET in the pediatric population or for conditions such as patulous ETD, systemic mucosal diseases, or autoimmune inflammatory diseases affecting the nasopharyngeal mucosa. While the American Academy of Otolaryngology-Head and Neck Surgery (AAO-HNS) consensus statement acknowledges that patients with a history of recurrent barochallenge might indicate a diagnosis of obstructive ETD, and that these patients may benefit from BDET, the studies conducted on this subgroup are small and heterogeneous.

Adult Population

Oehlandt et al (2022) assessed the efficacy and safety of balloon Eustachian tuboplasty (BET) for patients with baro-challenge-induced ETD by conducting a systematic review of the existing literature in November 2020, along with a retrospective cohort study of baro-challenge-induced ETD patients who underwent BET between 2011 and 2020. Additionally, a meta-analysis was performed to evaluate the Valsalva maneuver, ETDQ-7 score, and subjective symptom improvement. The systematic review resulted in inclusion of eight publications and the cohort study included altogether 113 patients. The authors reported an overall improvement in subjective symptoms after BET, showing improvement in 81% of patients, with 22 out of 27 (81%) professionals (professional divers, aviators, or cabin crew members) being able to continue in their profession. Reported complications were rare and mild. Outcome measures appear to be long-lasting based on a mean follow-up period of 4 years and 8 months. Although the authors concluded that BDET seems to be effective in baro-challenged-induced ETD and enables professionals to resume careers (flying or diving), they noted several study limitations (risk of bias was high in all studies, all studies lacked a control group, missing patient data, varied follow-up time and method) and note the need for more controlled and blinded studies on long-term effects.

Froehlich et al (2020) conducted a systematic review and meta-analysis of balloon dilation for chronic ETD. Twelve studies were included in the meta-analysis, including 3 randomized controlled trials (RCTs), 5 prospective observational studies, and 4 case series. One RCT (Liang et al 2016) that compared balloon dilation to tympanic paracentesis reported tympanometry and otoscopy scores but

not symptoms. The other two RCTs compared balloon dilation plus medical management to medical management alone and used the ETDQ-7 to measure symptoms. Pooled analyses showed improvements in subjective and objective measures including ETDQ-7 scores, tympanograms, otoscopy exams, and ability to perform a Valsalva maneuver. Improvements appeared to be maintained in studies with longer-term follow-up (3 to 12 months).

Poe et al (2018) conducted a 2:1 randomized controlled trial (n=323) to assess the safety and efficacy of BDET. Patients included in the study were aged 22 years and older who had persistent ETD and who had failed medical management, which consisted of either a minimum of four weeks of continuous daily usage of any intranasal steroid spray or a minimum of one completed course of an oral steroid within 90 days of study enrollment. A positive diagnosis of persistent ETD was confirmed with both abnormal tympanometry and symptomatic dysfunction, as determined by the Eustachian Tube Dysfunction Questionnaire (ETDQ-7). BDET was performed in the operating room under general anesthesia. Each dilation was done at an inflation pressure of 10-12 atm, with a total time of two minutes. The primary effectiveness endpoint was normalization of tympanometry at six-week follow-up. At the six-week follow-up period, 51.8% of the investigational group had a normal tympanogram versus 13.9% in the control group. At 24-weeks postoperatively, tympanogram normalization in the treatment group was 62.2%, however, the majority of the failed control group subjects had crossed over, so no statistical comparison could be made. Improvement in tympanometry was also associated with normalization of the ETDQ-7 at six-weeks. There were no serious adverse effects noted in the study, but two subjects did develop mild symptoms of patulous ET, one of which resolved by the completion of the study. The authors concluded that the study shows BDET, with adjunctive medical management, is superior to medical management alone. Study limitations include the inability to blind patients, short term follow-up, small sample size, and most patients in the control group (82%) did opt to crossover and receive BDET before their 12-week follow-up. As a result of this crossover, the control group became relatively small and self-selecting in nature, likely biasing any statistical comparison between treatment groups.

Anand et al (2019) published the 52-week follow up data to the 2017 Poe study. At 52 weeks, the overall results of tympanograms and ETDQ-7 questionnaires of subjects who received balloon dilation remained comparable to the results at the six-week follow-up period. Tympanograms were done at six weeks, 12 weeks, 24 weeks, and 52 weeks. At six weeks, the tympanogram results were 51% normalized; at 52 weeks, 55.5% were normalized. There were many instances in which ears had normalized tympanograms, then reverted to non-normalized tympanograms, then normalized tympanograms again. In total, 63.6% of ears had normalized tympanograms at 52 weeks, either remaining normal throughout the study or converting to normal (failure then becoming normal or temporary failure but return to normal). The authors concluded that the beneficial effects of BDET with medical management at the 52-week follow-up demonstrate a durability that is clinically relevant.

Meyer et al (2018) conducted a randomized controlled trial to compare BDET to continued medical therapy for treating persistent ETD. Subjects were randomized in a 1:1 ratio to balloon dilation or control (medical management). Of the 60 patients in the study, 31 patients were randomized to the balloon dilation group, and 29 were randomized to the control group. Patients were required to follow

up at six-weeks, and then at three-, six-, and 12-months post-procedure. Patients included in the study were aged 18 years and older, who had been diagnosed with ETD for 12 months or greater, had three or more symptoms, and had failed medical therapy of intranasal steroids or oral steroids. After six weeks, subjects in the control group had the option to undergo the procedure if their symptoms persisted. Comparison between baseline and post treatment was evaluated using an ETDQ-7. The study found that balloon dilation led to a significant reduction in overall ETDQ-7 scores, as well as statistically significant improvement in ETD symptoms and middle ear functional assessments. The authors concluded that BDET is a safe, effective, and durable treatment for ETD.

Huisman et al (2018) performed a meta-analysis to evaluate the success of BDET in reducing symptoms in adult patients with ETD. The search yielded 15 studies that met inclusion criteria for a total of 1,155 patients. Inclusion criteria involved studies that were BDET in adults with ETD. The studies evaluated improvement of ETD symptoms to measure effectiveness of treatments such as the Valsalva maneuver, otoscopy, tympanometry, and the ET score. Revisions due to failure of the first ET balloon dilation procedure were reported in three of the 15 studies, including 714 patients. Overall, the results from the studies included in the analysis found that all types of ETD showed an improvement in short-term follow-up, and the number of complications was relatively low. The authors recommended future research in randomized homogenous populations.

Pediatric Population

Aboueisha et al (2022) published a meta-analysis of BDET in children less than 18 years of age. A database search identified seven studies that examined the safety and efficacy of BDET in pediatric patients (n=408) from the database inception to March 2021. The evidence base included six retrospective cohort studies and one prospective cohort study with a matched retrospective control group. Among these studies, four were designed as single-arm investigations, while three studies compared the outcomes of BDET with ventilation tube insertion (VT). The pooled studies included a total of 408 children, averaging 9.9 years of age, with an average follow-up period of 19.2 months. In all but one study, patients had a history of prior surgeries, including VT plus adenoidectomy or VT alone. Aggregating data from all seven studies, the pooled complications exhibited an incidence rate of 5.1% (95% CI, 3.1 to 8.4), with self-limited epistaxis being the most frequently reported complication. No major adverse events were reported. Type A tympanograms increased from 15.1% to 73.6% (95% CI, 58% to 84.9%) and Type B tympanograms decreased from 64.2% in the pre-operative period to 16.1% (95% CI, 8.5 to 28.4). In the three studies that compared BDET to VT, a significant difference in the rate of failure (need for reoperation, persistent type B tympanogram, or persistence of symptoms) was observed, favoring the BDET group, however, high heterogeneity was observed across the three studies pooled for this estimate.

Although Aboueisha and colleagues noted several limitations (e.g., RCTs, small number of studies, that the BDET technique is not yet standardized, and different types of balloons were used during studies), they concluded that BDET with or without tympanostomy tube placement may produce outcomes that are comparable, if not superior to, tympanostomy tube placement alone in treating chronic otitis medica with effusion. The authors concluded the procedure was safe with no major adverse events, and future prospective RCTs may help better determine the best candidate in the pediatric population.

Saniasiaya et al (2022) performed a literature review to cover the current literature available on the outcomes of BDET in children. A literature search, conducted from 1990 to 2020, identified only seven articles which included six retrospective cohort case series and one cohort of matched controls. Of the 284 patients included in the review, a total of 463 balloon dilations were performed either bilaterally or unilaterally. The total number of patients for each study ranged from 1 to 66, with a mean age of 7.8 years. BDET was performed as a second-line treatment in six studies, whereas in one study, BDET was the first-line treatment for ETD. The most common finding of ETD was middle ear effusion, as demonstrated in five studies. No major complications were reported in all seven studies included. Minor complications were noted in four studies, with the most common minor complication includes serous otitis media in 13 patients and epistaxis in five patients. The authors concluded that BDET may be considered as an alternative procedure following failed standard treatment. However, the authors noted that the quality of evidence is inadequate to recommend widespread use of the technique until better quality studies are completed.

Gurberg et al (2024) conducted a retrospective matched cohort study of 20 pediatric patients, each from two centers in the United States, to report the long-term safety and efficacy of BDET compared with tympanostomy tube (TT) placement in the pediatric population. Inclusion criteria were patients aged less than 18 who were indicated for TT placement. All patients were successfully matched for number of prior TT, prior adenoidectomy, and gender. Of the 20 patients, 17 were matched exactly for age. Charts were retrospectively reviewed for demographics, tympanometry data, adjunctive procedures, and need for additional interventions. A total of 33 Eustachian tubes were dilated in 20 patients with a mean age of 7 years (range 1.2-14). The mean duration of follow-up was 6.7 years (SD 2.6; range 1.4 to 10.8 years). Over the follow-up time period, two patients failed in the BDET group vs. eight patients in the TT insertion group. Patients who underwent BDET had a lower risk of failure than patients who underwent TT insertion (adjusted HR: 0.18; 95=CI: 0.04, 0.81; p=0.03). The probability of being failure free at six years was 88% (95CI, 71- 95%) in the BDET cohort and 53% (95% CI, 33-70%) in the TT insertions cohort. There were no serious injuries reported in either group. Given that these results occurred in the absence of other interventions in the tympanic membrane, authors suggest the possibility that BDET could serve as a standalone procedure for the treatment of chronic otitis media with effusion. The limitations of the study include the small sample size, its retrospective nature, and the differences in location of the cohorts matched. Authors concluded that while the present study bolsters literature support for the use of BDET in patients with ETD refractory to standard surgical treatment, large randomized clinical trials with long term follow up are indicated.

Transtympanic BDET

There is insufficient peer-reviewed evidence to support the safety and efficacy of the transtympanic approach to BDET. The evidence includes a systematic review of studies, which included two case series on human subjects and one case series on human cadavers (Jufas and Patel, 2016). In 2018, Kapadia and colleagues evaluated the safety of transtympanic BDET of the cartilaginous proximal ET on 8 cadavers (15 ears). Kapadia and Tarabichi (2018) conducted a case series study to assess the safety and feasibility of transtympanic dilation of proximal (tympanic-end) of the cartilaginous segment of the Eustachian tube in patients (n=40) undergoing surgery for chronic ear disease. All

conclude that further study of the technique is warranted.

PROFESSIONAL GUIDELINE(S)

In 2019, the American Academy of Otolaryngology Head and Neck Surgery (AAO-HNS) developed clinical consensus statements on BDET (Tucci et al 2019). The target population was defined as adults ≥ 18 years who are candidates for BDET because of obstructive ETD in one or both ears for 3 months or longer that significantly affects quality of life or functional health status. The expert panel concluded that BDET is an option for treatment of obstructive ETD and reached consensus of 28 statements related to patient criteria, perioperative considerations, and outcomes. There were 28 other statements that the expert panel did not reach consensus, likely reflecting knowledge gaps regarding the role of BDET in managing OETD. This includes the role for repeat BDET, which was found to lack adequate literature to support the efficacy of repeat BDET if the first BDET has not been successful.

In 2019, the National Institute for Health and Care Excellence (NICE) published updated guidance on BDET. The guidance was based on a rapid review of the evidence and stated, "Evidence on the safety and efficacy of balloon dilation for Eustachian tube dysfunction is adequate to support the use of this procedure provided that standard arrangements are in place for clinical governance, consent and audit." The guidance also noted that the procedure was not effective in all patients, there was little evidence on the benefit of repeat procedures, and the procedure is only indicated for chronic ETD refractory to medical treatment.

Although the Food and Drug Administration (FDA) expanded clearance for one dilation system to be used for ages 8-17, there is no clinical practice guideline or consensus statement published for BDET in the pediatric population.

REGULATORY STATUS

The U.S. Food and Drug Administration (FDA) regulates balloon dilation systems as medical devices. All balloon dilation systems including related components require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2026 May 29]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most serious type of recalls. Available from: Medical Device Recalls | FDA [accessed 2026 May]

In September 2016, the Acclarent AERA Eustachian Balloon Dilation System (Acclarent, Inc.) was granted de novo classification by the FDA. Initially cleared for patients with persistent ETD aged 22 years and older, the system received FDA approval for ages 18 and older (K171761) in January 2018.

Based on real-world evidence, with data from published literature and data provided by established physicians, the FDA expanded the Acclarent AERA's indications for use to include patients ages 8 – 17 years (K230742) in December 2023. The system is indicated for use alone or in combination with adjunctive procedures, to treat objective signs of persistent obstructive ETD from inflammatory

pathology, resulting in chronic otitis media with effusion and are refractory to at least one surgical intervention for persistent obstructive ETD.

In December 2016, the XprESS ENT Dilation System (Entellus Medical) was also cleared for marketing by the FDA through the 510(k) process for two indications. Specifically related to ETD, the device is cleared for patients 18 years and older using a transnasal approach. The FDA determined that the device was equivalent to existing devices used for ETD.

In August 2021, the NuVent Eustachian Tube Dilation Balloon (Medtronic Xomed, Inc.) was cleared for marketing through the 501(k) process to treat persistent ETD in patients 18 years and older (K210841).

In August 2023, the TubaVent Balloon Dilatation System (Spiggle & Theis Medizintechnik, Germany) received FDA 510(k) premarket notification clearance (K223542) for the indicated use of dilating the cartilaginous portion of the Eustachian tube for treatment of persistent obstructive ETD in patients 18 years and older.

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
31231	Nasal endoscopy, diagnostic, unilateral or bilateral (separate procedure)
69705	Nasopharyngoscopy, surgical, with dilation of Eustachian tube (i.e., balloon dilation); unilateral
69706	Nasopharyngoscopy, surgical, with dilation of Eustachian tube (i.e., balloon dilation); bilateral
69799	Unlisted procedure, middle ear
92511	Nasopharyngoscopy with endoscope (separate procedure)

MEDICAL POLICY

Medical Policy Title	**Bariatric and Metabolic Surgery**
Policy Number	**7.01.29**
Current Effective Date	**January 1, 2026**
Next Review Date	**May 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. The surgical treatment of obesity by Roux-en-Y gastric bypass (open or laparoscopic), biliopancreatic diversion with duodenal switch (BPD-DS), single-anastomosis duodenoileal bypass with sleeve gastrectomy (SADI-S), laparoscopic adjustable gastric banding (LAGB), and sleeve gastrectomy is considered **medically appropriate** when **ALL** of the following criteria are met:

A. The individual's body mass index (BMI) meets **one (1)** of the following:

Adult

1. Class 3 obesity (BMI 40 kg/m^2 or greater);
2. Class 2 obesity (BMI 35 to 39.9 kg/m^2) and at least one (1) obesity-related comorbidity (e.g., cardiovascular disease, dyslipidemias, hypercholesterolemia, hypertension, metabolic syndrome, non-alcoholic fatty liver disease, pulmonary hypoventilation, obstructive sleep apnea, or weight-bearing joint arthropathy); **or**
3. Class 1 obesity (BMI 30 to 34.9 kg/m^2) and type 2 diabetes (T2D) with documentation of inadequate glycemic control despite optimized lifestyle and medical management; **or**

Adolescent

4. Class 3 obesity (BMI greater than or equal to 40 kg/m^2, or BMI greater than or equal to 140% of the 95th percentile, whichever is lower based on age and sex); **or**
5. Class 2 obesity (BMI 35 to 39.9 kg/m^2, or BMI between 120% to 139.9% of the 95th percentile, whichever is lower based on age and sex), and at least one (1) obesity-related comorbidity (e.g., cardiovascular disease, dyslipidemias, hypercholesterolemia, hypertension, metabolic syndrome, non-alcoholic fatty liver disease, pulmonary hypoventilation, obstructive sleep apnea, type 2 diabetes, or weight-bearing joint arthropathy);

B. Documentation of the individual's participation efforts to achieve weight loss or metabolic improvements including **all** of the following:

1. Pre-operative lifestyle and medical optimization efforts including the type of the weight-loss/nutritional program(s), applicable medication(s), length of participation, and results

achieved (e.g., weight loss, lowered hemoglobin A1C). Documentation can be provided by the bariatric surgeon, primary care provider, registered dietician, or nutritionist;

2. Pre-operative nutrition evaluation conducted by a registered dietician is mandatory; **and**
3. Planned participation in a post-operative weight management program through the first year after surgery that supports long-term health outcomes through nutritional management (including assessment for malabsorption), physical activity, and behavioral health support;

C. Medical clearance attestation for surgery from the primary care provider or bariatric surgeon;

D. Behavioral health clearance for surgery is documented by **either** of the following:

1. The bariatric surgeon or primary care provider documents the absence of any psychiatric or psychosocial comorbidities; **or**
2. A licensed behavioral health provider familiar with the implications of weight loss surgery is required for **either** of the following:
   a. history of alcohol or substance use disorder with 6 months or less of abstinence; **or**
   b. psychosocial, psychological, or psychiatric concerns identified by any member of the bariatric pre-operative evaluation team.

II. Bariatric and metabolic surgery as a treatment for individuals with a BMI less than or equal to 29.9 kg/m^2 is considered **investigational.**

III. The following procedures for the surgical treatment of obesity are considered **investigational**:

A. Laparoscopic gastric plication (also known as laparoscopic greater curvature plication);

B. One anastomosis gastric bypass (OAGB) (also known as mini-gastric bypass);

C. Vertical banded gastroplasty (VBG);

D. Intragastric space occupying mechanisms (e.g., intragastric balloon or expanding material/capsules);

E. Endoscopic/endoluminal procedures or devices, including but not limited to:

1. Gastric aspiration therapy;
2. Transoral gastroplasty (TOGA, also known as vertical sutured gastroplasty, endoluminal vertical gastroplasty, System);
3. Restorative obesity surgery endoluminal (ROSE);
4. Closure/plication and suturing (e.g., StomaphyX, EndoCinch, Apollo Overstitch)
5. TransPyloric Shuttle;
6. Gastrointestinal liners (e.g., duodenal-jejunal bypass liners such as EndoBarrier); and
7. Endoscopic sleeve gastroplasty (ESG);

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

8. Transoral outlet reduction [TORe]).

Revisional and Corrective Surgery

IV. Surgical revision is considered **medically necessary** for documented complications following the primary procedure (e.g., malabsorption or malnutrition, obstruction, or stricture, staple-line disruption, severe gastroesophageal reflux disease that does not respond to medical treatment).

V. LAGB revision or removal is considered **medically appropriate** for documented complication(s) or technical failure(s) (e.g., band slippage, band erosion, infection, esophageal dilation, dysphagia, heartburn/reflux, displaced band, port dislocation band intolerance [e.g., pain or vomiting], and port and/or catheter leakage).

VI. Revision or conversion to another medically appropriate procedure due to inadequate weight loss or metabolic improvement following the primary bariatric procedure is considered **medically appropriate** when **BOTH** of the following are met:

   A. Documented compliance to the prescribed post-operative nutrition and physical activity program for at least 6-months;

   B. **Either** of the following are met:

      1. Non-response to the primary procedure (failure to achieve adequate outcomes); **or**

      2. Weight recurrence following initial successful weight reduction from the primary procedure.

VII. Reoperation or revision surgical treatment of obesity is considered **investigational** for **EITHER** of the following:

   A. Placement of a second adjustable gastric band (AGB);

   B. Endoscopic/endoluminal procedures (e.g., transoral outlet reduction [TORe], endoscopic sleeve gastroplasty [ESG]).

Concomitant Procedures

VIII. Performing a routine liver biopsy at the time of the bariatric surgery is considered **not medically necessary** in the absence of documented signs or symptoms of liver disease (e.g., abnormal liver function tests of unknown etiology, knowledge of a specific diagnosis that will likely alter the treatment plan, known liver disease where prognostic information about fibrosis may guide subsequent treatment, the presence of a mass or lesions, or focal or diffuse abnormalities seen on imaging studies of unknown etiology).

IX. Prophylactic removal of a normal and asymptomatic gallbladder at the time of bariatric surgery is considered **not medically necessary**, unless cholelithiasis is present, or the patient will undergo biliopancreatic diversion with or without duodenal switch based on a higher incidence of biliary complications.

RELATED POLICIES

Corporate Medical Policy

7.01.64 Gastric Electrical Stimulation

11.01.03 Experimental or Investigational Services

POLICY GUIDELINE(S)

I. Body mass index (BMI) requirements are based on preoperative measurements. BMI is calculated by dividing a person's weight in kilograms (kg) by the square of height in meters (m^2).

II. BMI thresholds may be adjusted for ethnicity (e.g., Asian population) on a case-by-case basis. Obesity definitions using BMI thresholds do not apply similarly to all populations, clinical obesity in the Asian population is recognized in individuals with BMI >25 kg/m^2 (Eisenberg 2022).

III. Individuals considering surgery must participate in a multidisciplinary pre- and post-operative lifestyle modification program that addresses long-term commitment and management of modifiable risk factors (e.g., dietary changes, nutritional monitoring, physical activity, behavioral modification, and psychosocial support). The post-operative plan must include participation in ongoing postoperative follow-up through the first year after surgery.

IV. Revision or conversion surgery may be performed for weight recurrence, non-response, or post-operative symptoms (e.g., gastroesophageal reflux disease) that do not respond to medical management.

   A. Surgery for medical complication(s) or technical failure(s) does not require adherence to post-operative follow-up recommendations.

   B. Surgery for weight recurrence or non-response requires documented adherence to post-operative program recommendations for at least six (6) months.

V. The American Society of Metabolic and Bariatric Surgery (ASMBS) reiterates that a multidisciplinary team should evaluate patients to optimize surgical outcomes including:

   A. Comprehensive preoperative assessment of medical history, physical examination, laboratory testing (e.g., H. pylori, kidney function, liver profile, thyroid stimulating hormone), psychosocial history (e.g., functioning, substance use, maladaptive eating patterns), lifestyle/nutritional evaluation (e.g., sleep hygiene, smoking, healthy eating index) (Carter 2021; Mechanick 2019).

   B. Pre-operative optimization refers to the management of modifiable risk factors prior to elective surgery, with the goal of reducing the risk of perioperative complications and improving outcomes by implementing interventions that can address disordered eating, severe uncontrolled mental illness, or active substance abuse (Carter 2021; Eisenberg 2022).

VI. Adult classification of obesity by BMI (National Heart, Lung, and Blood Institute [NHLBI] 1998):

- Class 1 obesity: BMI 30 to 34.9 kg/m^2

- Class 2 obesity: BMI 35 to 39.9 kg/m^2
- Class 3 extreme obesity: BMI 40 kg/m^2 or greater

VII. Child and adolescent BMI interpretation is age- and sex-specific with weight category and classification of (Hampl 2023):

- Class 2 obesity: BMI 35 to 39.9 kg/m^2 or BMI between 120% to 139.9% of the 95th percentile
- Class 3 obesity: BMI greater than or equal to 40 kg/m^2 or BMI greater than or equal to 140% of the 95th percentile

VIII. The behavioral health evaluation should be performed by a licensed behavioral health provider familiar with the implications of weight reduction surgery. A current licensed behavioral health provider familiar with the implications of weight reduction surgery who provides ongoing care for the patient may also provide this evaluation. For psychological testing criteria, refer to the Related Policies section.

IX. Adolescents should be referred to an accredited pediatric/adolescent bariatric surgery program, such as a Surgical Review Corporation (SRC) or a Metabolic and Bariatric Surgery Accreditation and Quality Improvement Program (MBSAQIP) accredited pediatric program to ensure care in programs that meet established standards for patient safety and quality.

X. Coverage is limited to physicians who have been properly trained in performing a bariatric procedure at facilities with the diagnostic and support services necessary for the care of morbidly obese patients.

XI. Any device used for bariatric surgery must be used in accordance with the approved indications of the United States Food and Drug Administration (FDA).

XII. An expected outcome of successful bariatric surgery is redundant/excessive skin.

XIII. The adjustment of a previously placed laparoscopic adjustable gastric band (LAGB), beyond the global, 90-day limit, controls the rate of weight loss and/or treat symptoms secondary to gastric restriction following the initial medically necessary adjustable gastric banding procedure. Adjustment of LAGB is performed via accessing the subcutaneous port, with or without imaging).

DESCRIPTION

Obesity is a complex multifactorial condition that substantially increases the risk of weight-related complications and comorbidities associated with excess adiposity. Complications may include, but are not limited to asthma, nonalcoholic fatty liver disease, hypertension, dyslipidemia, pre-diabetes, type 2 diabetes, metabolic syndrome, coronary artery disease, stroke, gallbladder disease, osteoarthritis, obstructive sleep apnea, respiratory problems, and a variety of certain types of cancers (e.g., colorectal cancer). BMI is a measure used to screen for excess body adiposity (body fat) and is calculated by dividing a person's weight in kilograms (kg) by the square of height in meters (m2).

Clinically severe obesity includes class III obesity (formerly referred to as morbid obesity) and class II obesity with associated comorbid conditions (NHLBI 1998). The NHLBI outlines the following

relationship between overweight/obesity BMI and disease risk, which is noted to vary among individuals and different populations:

Obesity Classification	BMI (kg/m^2)	Disease Risk*
Overweight	25.0-29.9	Increased
Class 1 obesity	30-34.9	High
Class 2 obesity	35-39.9	Very High
Class 3 extreme obesity	>40	Extremely High

*Disease risk for type 2 diabetes, hypertension, and cardiovascular disease.

The first line of treatment for obesity is dietary and lifestyle modification, including intensive lifestyle intervention (ILI). Under medical supervision ILI programs include comprehensive behavioral management strategies that focus on improving dietary habits, increasing physical activity, and enhancing self-care and psychological well-being. Strong evidence suggests that multidomain ILI reduces cardiovascular risk factors among persons with type 2 diabetes (Huckfeldt 2023). Although this strategy may be effective in some individuals, not all individuals can reduce and control weight through diet and activity/exercise/movement. When conservative measures fail, some individuals consider surgical approaches.

Bariatric surgery, also referred to as metabolic or bariatric surgery (MBS), is an evidence-based option for individuals with class II or III obesity who have not achieved sufficient weight loss through non-surgical interventions. Long-term evidence demonstrates significant and durable clinical improvement, and in some cases remission, of co-morbidities (e.g., type 2 diabetes). Bariatric or metabolic surgery works by changing the anatomy and size of the stomach to reduce/restrict food intake, as well as modifying the digestion process to improve fat metabolism. Some procedures can also affect the production of intestinal hormones, which can influence appetite and metabolic improvements.

Bariatric and metabolic surgery for individuals with class I obesity and T2D is increasingly performed based on evidence showing improvement or remission of diabetes following surgery, sometimes occurring before substantial weight loss. Various surgical procedures have different effects on weight loss. Gastrointestinal rearrangement appears to confer antidiabetic benefits independent of weight loss and caloric restriction, although the precise mechanisms remain under investigation. Proposed mechanisms include changes in gastrointestinal peptides such as glucagon-like peptide-1 (GLP-1), glucose-dependent insulinotropic peptide (GIP), and peptide YY (PYY). GLP-1, secreted by L cells in the distal ileum, enhances glucose-dependent insulin secretion, slows gastric emptying, blunts postprandial glycemia, and promotes satiety. GIP acts on pancreatic beta cells to increase insulin secretion, while PYY contributes to satiety and delayed gastric emptying. These hormonal changes may also improve insulin sensitivity.

Bariatric surgery is generally categorized into two types: gastric restrictive procedures and malabsorptive procedures. Restrictive procedures mechanically limit the volume of food intake before

satiety is achieved, while malabsorptive procedures reduce nutrient absorption by altering the normal digestive pathway. Many operations combine both mechanisms.

Procedures/Interventions

Roux-en-Y gastric bypass (RYGB) combines restrictive and malabsorptive components. The stomach is partitioned horizontally or vertically and connected to the jejunum via a Roux-en-Y configuration, bypassing the duodenum and proximal small bowel. This procedure can be performed via open or laparoscopic techniques. Potential complications include dumping syndrome, anastomotic complications, (e.g., leakage or marginal ulceration), and nutritional deficiencies due to altered absorption (e.g., iron, vitamin B-12, and calcium).

Sleeve gastrectomy (SG) involves resection of the greater curvature of the stomach from the angle of His to the distal antrum, creating a tubular gastric remnant. The pylorus is preserved, allowing more physiological gastric emptying and reducing the risk of dumping syndrome. SG may serve as a standalone procedure or as a first stage before a more extensive malabsorptive operation (e.g., BPD).

Adjustable gastric banding (AGB) uses a laparoscopically placed band around the upper stomach, connected to a subcutaneous reservoir for saline injection. Adjustments alter stoma size to regulate food passage. Complications include band slippage, erosion, and port-related issues.

Biliopancreatic diversion (BPD), also known as the Scopinaro procedure, combines subtotal gastrectomy with diversion of biliopancreatic secretions to the distal ileum via a long Roux-en-Y limb. This procedure carries significant risks, including protein malnutrition, iron deficiency anemia, hypocalcemia, and bone demineralization. BPD with duodenal switch (DS) modifies BPD by replacing distal gastrectomy with sleeve gastrectomy, preserving the pylorus and proximal duodenum. This reduces dumping syndrome and ulcer risk while maintaining selective malabsorption.

Single-anastomosis duodeno-ileal bypass with sleeve gastrectomy (SADI-S), also known as stomach-intestine pylorus-sparing surgery (SIPS), combines SG with a single duodeno-ileal anastomosis, preserving the pylorus and reducing complexity compared to DS. It aims to minimize risks such as short bowel syndrome while maintaining malabsorptive benefits.

Gastric plication is a restrictive laparoscopic procedure that reduces gastric volume by folding and suturing the stomach without tissue resection.

Vertical banded gastroplasty (VBG) creates a small pouch by vertically stapling and horizontally banding the upper stomach. This once common legacy procedure has largely been abandoned due to high revision rates from complications such as staple line disruption and band erosion.

Reversal or Revisional Surgery

Professional society guidance recognizes the role of revisional procedures to address device- or procedure-related complications, technical failures, or inadequate outcomes following prior bariatric interventions. Endoscopic revision, including TORe and repeat gastric remodeling using suturing techniques (e.g., repeat ESG/re-suturing patterns), is described as a stepwise strategy to manage weight regain or anatomic dilation after prior endoscopic or surgical procedures.

Procedures are generally not indicated when failure is attributable to noncompliance with recommended dietary and behavioral protocols, such as gastric pouch dilation resulting from overeating.

Endoscopic and Device-Based Procedures

As revisional metabolic and bariatric surgery (MBS) is associated with a higher complication rate than primary MBS, there is interest in endobariatric revisional procedures to treat weight related issues while potentially minimizing the risk of complications (Docimo 2026). The primary goals vary by intervention type, with gastric endoscopic bariatric and metabolic therapies (EBMTs) primarily targeting weight loss, whereas small-bowel interventions focus on glycemic improvement as the primary efficacy endpoint, with weight loss assessed as a co-primary or secondary outcome (e.g., duodenal–jejunal bypass liner).

Endoscopic suturing is an endoscopic tissue-approximation technique used to place full-thickness sutures or plications within the gastrointestinal tract and is used to perform several EBMTs and revisional procedures, including endoscopic sleeve gastroplasty (ESG) and other gastric remodeling procedures. Specialized devices (e.g., EndoCinch, Apollo OverStitch) place stitches inside the gastrointestinal tract.

Endoscopic gastric remodeling (EGR) refers to a group of endoscopic interventions that use endoscopic tissue-approximation technologies to remodel the stomach, reduce gastric volume, alter motility, and promote early satiety. EGR encompasses ESG and includes multiple devices (e.g., Apollo ESG System/OverStitch, POSE system, and Endomina).

Endoscopic sleeve gastroplasty (ESG) is a minimally invasive endoscopic procedure that reduces gastric volume by creating full-thickness plications along the greater curvature of the stomach using endoscopic suturing to produce a sleeve-like gastric remodeling and clinically meaningful weight loss. ESG mimics the restrictive effect of sleeve gastrectomy without gastric resection. Endoscopic "resleeve" gastroplasty has been described as an endoscopic option for revision following sleeve gastrectomy.

Transoral outlet reduction (TORe) is an endoscopic revisional procedure for weight regain after Roux-en-Y gastric bypass due to dilation of the gastrojejunal anastomosis (GJA). Techniques to reduce anastomotic diameter, to support satiety and weight control, include endoscopic suturing, argon plasma coagulation (APC), or both

Transoral gastroplasty (TG), also known as vertical sutured gastroplasty or endoluminal vertical, is an endoluminal approach intended to create gastric restriction using incisionless or stapling-based (e.g., TOGA) to create a restrictive gastric pouch.

Intragastric balloons (e.g., Orbera, Obalon, Spatz3) are temporary, endoscopically placed balloons that reduce gastric capacity to promote satiety. They are used for short-term weight loss or as a bridge to definitive surgery.

Aspiration therapy (AT) uses a percutaneous gastrostomy tube to aspirate gastric contents post-meal, reducing caloric absorption. Success depends on individual adherence.

TransPyloric shuttle (TPS) is an endoscopically inserted device that intermittently obstructs the pylorus to delay gastric emptying, promoting early and prolonged satiety.

Small-bowel interventions include the duodenal–jejunal bypass liner (DJBL) (e.g., EndoBarrier), which limits nutrient contact with the proximal small intestine and is evaluated primarily for glycemic improvement. Duodenal mucosal resurfacing (DMR) is an endoscopic treatment to ablate the duodenal mucosa in an attempt to improve diabetes mellitus and fatty liver disease in patients with obesity.

SUPPORTIVE LITERATURE

The 1991 National Institute of Health (NIH) Consensus Statement first supported the safety and effectiveness of bariatric surgery. The Swedish Obese Subjects (SOS) trial, the most influential study comparing bariatric surgery to conservative treatment, demonstrated substantial weight loss, improved comorbid conditions, and enhanced quality of life after surgery (Sjostrom 2007).

Class II and III Obesity

There is sufficient published medical literature demonstrating the safety and efficacy of specific bariatric procedures including: open or laparoscopic Roux-en-Y gastric bypass procedures (Himpens 2012; Wadden 2019; Cui 2021; Angrisani 2021), sleeve gastrectomy (Leyba 2011; Himpens 2010; D'Hondt 2011; Chouillard 2011; Wolnerhanssen 2021; Vitiell 2023), adjustable gastric band (Dixon 2008; Himpens 2011), biliopancreatic diversion with duodenal switch (Prachand 2006; Strain 2007; Skogar 2017), and SADI-S (Dijkhorst 2021; Esparham 2023; Axer 2024).

Class III Obesity with BMI ≥45 kg/m^2

Pereira et al (2024) conducted a prospective, interventional, open-label randomized study that assessed weight trajectories and postprandial endocrine/metabolic responses through 12 months in adults with class III obesity (BMI 45–55 kg/m²). Participants were randomized to SADI-S (n=7) or to sleeve gastrectomy (SG) as the first step of a planned two-step SADI-S (n=7). Study visits occurred pre-operatively and at 3, 6, and 12 months. Anthropometric, metabolic, and micronutrient profiles did not differ significantly between groups at baseline or at follow-up. Fasting and postprandial glucose, insulin, C-peptide, ghrelin, insulin secretion rate, and insulin clearance during the mixed-meal tolerance test (MMTT) were not significantly different between SADI-S and SG. No participants were lost to follow-up. At 12 months, the study reports no significant between-group differences in the clinical and metabolic outcomes assessed.

Esparham et al (2025) performed a systematic review and meta-analysis comparing duodenal switch (DS) and Roux-en-Y gastric bypass (RYGB) in patients with BMI ≥ 50 kg/m² (12 studies; n=2,678; 1–15 years follow-up). DS showed significantly greater BMI reduction ($p < .001$) and greater total weight loss ($p < .001$) than RYGB. Complication, reoperation, mortality, and comorbidity remission rates (diabetes, hypertension, dyslipidemia, obstructive sleep apnea) did not differ significantly between groups. However, DS was associated with higher malnutrition rates (8.3% vs. 1.2%; $p = .02$), more revisional surgeries for malnutrition (5.4% vs. 0%; $p = .05$), and increased gallbladder disease requiring cholecystectomy (24.6% vs. 4.5%; $p = .01$). The authors concluded that DS

provides superior weight loss for patients with BMI ≥50 kg/m² but carries a higher risk of major malnutrition and revisional surgery compared to RYGB.

Class I Obesity with Type 2 Diabetes

Bariatric surgery as treatment for class 1 obesity and type 2 diabetes is supported meta-analysis and systematic reviews (e.g., De Luca 2023) which have found significantly greater remission rates of diabetes, decrease in HbA1c levels, and decrease in BMI with bariatric surgery than with nonsurgical treatment. Supporting randomized controlled trials (RCTs) include the STAMPEDE 5-year outcomes, which demonstrated that RYGB and SG were superior to intensive medical therapy for individuals with BMI 27–43 (Schauer 2017). The Alliance of Randomized Trials of Medicine vs Metabolic Surgery in Type 2 Diabetes (ARMMS-T2D) 3-year follow-up showed durable metabolic benefit with bariatric surgery compared with medical/lifestyle interventions across RYGB, SG, and adjustable gastric banding (Kirwan 2022), and 12-year long-term ARMMS-T2D data demonstrating sustained, clinically significant improvements in glycemic control, higher diabetes remission rates, and reduced need for diabetes medications after surgery (Courcoulas 2024).

Class I Obesity without Type 2 Diabetes

Evidence is limited for individuals with a BMI 35 kg/m^2 who do not have type 2 diabetes. A few small randomized controlled trials and case series have reported weight loss and improvements in comorbidities in this population; however, the available evidence does not allow conclusions regarding the long-term risk-benefit profile of bariatric surgery for these individuals.

One-Anastomosis Gastric Bypass (OAGB),

OABG, formerly known as mini-gastric bypass or loop gastric by-pass lacks sufficient published in the medical literature to draw conclusions about the safety and effectiveness of the procedure.

Robert et al (2024) reported the 5-year extension study of the YOMEGA trial, a prospective, open-label, non-inferiority, randomized controlled trial done across nine high-volume bariatric institutions in France, enrolling adults aged 18–65 years with BMI ≥ 40 kg/m² or BMI ≥ 35 kg/m² with ≥1 comorbidity, and excluding those with severe gastro-esophageal reflux disease (GERD), Barrett's esophagus, or prior bariatric surgery (OAGB used a 200-cm biliopancreatic limb). A total of 127 participants were assigned to OAGB and 121 to RYGB, with scheduled assessments at 1, 3, 6, 12, 18, and 24 months and annually thereafter; at 5 years, OAGB was non-inferior to RYGB for percentage excess BMI loss, and there was no significant between-group difference in the frequency of type 2 diabetes remission, while the mean decrease in HbA1c from 2 to 5 years did not differ between procedures. Diarrhea decreased from 2 to 5 years in the OAGB arm while increasing in the RYGB arm; early dumping syndrome at 5 years was more frequent with RYGB than OAGB; and GERD increased over time in both groups but was significantly higher after OAGB, with greater proton-pump inhibitor use; ten OAGB patients were converted to RYGB during follow-up. The investigators noted that malabsorption-related adverse events improved over time in the OAGB group (no hospitalizations for malnutrition from years 2–5 after nine serious malnutrition events within the first 2 years). Although the authors concluded that OAGB was non-inferior to RYGB for weight and metabolic outcomes at 5 years, the higher frequency of GERD after OAGB supports the need for

ongoing surveillance. Study limitations include substantial loss to follow-up at 5 years, reliance on symptom-based GERD assessment rather than standardized reflux testing, and a relatively small diabetes subgroup, all of which may affect the precision and generalizability of adverse-event and metabolic outcome estimates.

Endobariatric Procedures

Mrad et al (2025) conducted a network meta-analysis of randomized trials comparing any of the currently commercially available endoscopic bariatric therapies (EBTs) with controls, either sham procedures or diet plus lifestyle interventions for patients with obesity or overweight. Ten and eight studies were eligible for qualitative and quantitative analysis, respectively. The authors concluded that, considering percentage of total weight loss (%TWL) at the time of IGB removal, all EBTs were associated with statistically higher % TWL than controls. There were no significant differences among EBTs. All currently available EBTs approved by the U.S. Food and Drug Administration (FDA) are more effective than both diet plus lifestyle intervention and sham procedures with an acceptable safety profile. ESG seems the most effective and may be prioritized for patients fit for both ESG and IGBs; however, direct controlled trials between EBTs are warranted to confirm these findings.

Docimo et al (2026) with the American Society for Metabolic and Bariatric Surgery (ASMBS) conducted a systematic review of pertinent endoluminal bariatric therapies for both primary and revisional indications. Available evidence has shown intragastric balloons (IGBs) to be associated with percent total weight loss (%TWL) ranging from 4–13% across most studies, with a serious adverse event rate of less than 2%. The majority of studies do not report outcomes beyond one year; therefore, long-term effects on weight remain unknown and require further investigation in the context of treating a chronic disease. Available evidence for endoscopic sleeve gastroplasty (ESG) shows favorable improvement in weight (excess weight loss [EWL] of 45–60%) and metabolic disease. Although laparoscopic sleeve gastrectomy (LSG) consistently demonstrates greater improvement in weight loss and comorbidities, ESG may be a suitable option for patients who are unable or unwilling to undergo LSG. Based upon current results, endoluminal duodenal-jejunal liners in their present form remain investigational. The literature for transoral outlet reduction (TORe) reports modest weight loss (%TWL 7–8%) up to one year after treatment, with weight regain observed between 6 and 12 months, and no longer-term follow-up available. Techniques including full-thickness endoscopic suturing alone, argon plasma coagulation (APC) alone, and suturing combined with APC have all been described without clear evidence of superiority among methods. The ASMBS concluded that obesity is a chronic disease best treated in a multidisciplinary setting. Therefore, endoluminal bariatric procedures should be performed within a multidisciplinary program that provides longitudinal support for patients with obesity over time and facilitates ongoing data collection on patient outcomes.

Endoscopic Sleeve Gastroplasty (ESG)

Abu Dayyeh et al (2022) conducted a prospective, multi-center, randomized trial (MERIT) with individuals (n=209) aged 21-65 with class I or class II obesity and who agreed to comply with lifelong dietary restrictions. Participants were randomly assigned (1:1) to ESG with lifestyle modifications (ESG group; n=85) or lifestyle modifications alone (control group; n=124), with

potential retightening or crossover to ESG, respectively, at 52 weeks. Participants in the primary ESG group were followed up for 104 weeks. At 52 weeks, the primary endpoint of mean percentage of EWL was 49.2% for the ESG group and 3.2% for the control group ($p<0.0001$). Mean percentage of total bodyweight loss was 13.6% for the ESG group and 0.8% for the control group ($p<0.0001$). At 52 weeks, 41 (80%) of 51 participants in the ESG group had an improvement in one or more metabolic comorbidities, whereas six (12%) worsened, compared with the control group in which 28 (45%) of 62 participants had similar improvement, whereas 31 (50%) worsened. At 104 weeks, 41 (68%) of 60 participants in the ESG group maintained 25% or more of EWL. ESG-related serious adverse events occurred in three (2%) of 131 participants, without mortality or need for intensive care or surgery. Study limitations include the absence of a sham intervention group, inadequate cohort size, and follow-up to detect differences outcomes.

Docimo et al (2023), on behalf of the American Society for Metabolic and Bariatric Surgery Clinical Issues Committee, published a systematic review of the peer-reviewed literature on endoscopic sleeve gastroplasty (ESG) and primary obesity surgery endoluminal procedures (POSE, POSE 2.0), collectively regarded as alternative forms of endoscopic sutured gastroplasty. The panel noted that most published studies used ESG in patients with a BMI of 30–40 kg/m², with limited data available for patients outside this range. Across multiple studies, ESG yielded an average total body weight loss of 13%–20% at 12 months, which was significantly less than the weight loss observed after laparoscopic sleeve gastrectomy in comparative analyses. Among the studies reporting 2- and 3-year outcomes, most demonstrated sustained weight loss. ESG was also associated with improvements in metabolic disease, and postoperative surveys across several studies indicated a <3% incidence of de novo GERD. With similar weight-loss outcomes and complication rates, POSE and POSE 2.0 represent alternative endoluminal plication techniques to ESG. Endoscopy may be performed in advance or as the first step of a single-stage conversion. For practices offering ESG or POSE, these procedures should be integrated within a comprehensive multidisciplinary bariatric program, optimally within a bariatric center of excellence.

Abad et al (2025) conducted a prospective, multicenter, randomized, controlled, and double-blind study to evaluate the effectiveness and safety of ESG (with OverStitch) in patients with metabolic dysfunction-associated steatohepatitis (MASH). A total of 40 patients were randomized 1:1 to ESG plus lifestyle modification vs sham endoscopy plus lifestyle intervention. Inclusion criteria included biopsy-proven MASH with nonalcoholic fatty liver disease activity score (NAS) ≥3 and fibrosis stage F0 to F3. At the 72-week follow-up, 18 participants from the ESG group and 19 in the endoscopic simulated intervention (ESI) group completed the study. From baseline to the end of follow-up, total body weight loss was significantly greater with ESG than ESI ($P < .05$). ESG also resulted in significantly greater reductions in liver stiffness ($P < .05$) and steatosis ($P = .033$). In patients achieving weight loss >10%, there was significant improvement on NAS score ($p < .01$), but not in fibrosis stage. Only two patients in the ESG group had an adverse event, which resolved conservatively. Study limitations may limit generalizability and long-term inference, including a small sample, the single-disease population (MASH), and trial duration. The authors concluded that the results suggest that ESG may be an effective alternative therapy in the treatment of patients with MASH and should be used as part of second-line treatment, with or without other complementary

weight loss therapies, especially in patients who do not respond to lifestyle modification. Further studies are needed to confirm these findings and to better characterize its potential role in the management of patients with MASH.

Duodenal-Jejunal Bypass Liner (DJBL)

There is insufficient published evidence to establish DJBL safety and clinical efficacy.

Glaysher et al (2021) published a sub-study of a multicenter, randomized, controlled trial of patients within two treatment groups (n=70 per group) diagnosed with type-2 diabetes mellitus and BMI 30-50 kg/m^2. The authors reported that one year of DJBL therapy is associated with significantly greater weight loss and greater reduction in cholesterol; however, DJBL depleted essential fatty acids (EFAs).

Ruban et al (2022) conducted an open-label RCT of 170 adults with inadequate controlled T2DM and obesity. The authors reported there was no significant difference in the percentage of patients achieving a glycated hemoglobin reduction of at least 20%, and 16 patients (24%) achieved at least 15% weight loss in the DJBL group compared to 2 patients (4%) in the control group at 12 months.

Hollenbach et al (2024) reported on a RCT of 33 patients (11 DJBL, 15 intragastric balloon, and 7 sham group) which was terminated early after the DJBL device lost its CE mark in Europe. The authors concluded that, despite the lack of power, the data strongly suggest that intragastric balloon and DJBL lead to comparable weight loss while implanted; however, these procedures failed to achieve effective weight loss 12 months after explantation.

Chen et al (2024) conducted a systematic review and meta-analysis of 30 studies (1751 patients), concluding that DJBL offers significant improvement in weight loss, glycemic control, and cardiovascular parameters while in situ; however, recommended that further studies are warranted to better understand the long-term efficacy and safety of DJBL and that the benefits of DJBL need to be carefully weighed against the risks in clinical decision-making.

Gastric Plication

Research preliminarily supported that the procedure has acceptable short-term complication rates and weight loss outcomes (e.g., Fried 2012; Skrekas 2011; Kourkoulos 2012; Talebpour 2012); however, additional well-designed comparative studies with established bariatric procedures are needed, to determine its overall safety, efficacy, and impact on health outcomes.

Intragastric Space Occupying Devices

Published finding are insufficient and further studies are needed to demonstrate the long-term effects of utilizing intragastric balloon as a weight loss strategy (Ponce 2015; Bazerbachi 2018; Hollenback 2024; Silva 2024; Mrad 2025).

Dang et al (2018) performed a propensity-matched analysis between IGB and laparoscopic bariatric surgery (LBS) to compare safety profiles, concluding that IGB was associated with a higher adverse event rate than LBS, more research is needed, and IGB appears less safe than bariatric surgery as a standalone weight loss intervention.

Sullivan et al (2018) conducted a 24-week, double-blinded, randomized, sham-controlled trial of the

Obalon 6-month swallowable gas-filled IGB system (Carlsbad, CA) at 15 academic and private practice centers in the United States. Adults aged 22–60 years with BMI 30-40 kg/m^2 were randomized to receive either treatment (n=198) or control (n=209). Among participants who completed the 24 week treatment mean percent total body weight loss was 7.1% ± 5.0% in the treatment group and 3.6% ± 5.1% in the control group, for a mean difference of 3.5% (p = 0.0085). Although balloons were removed after 24 weeks, 89% of the treatment group maintained weight loss through 48 weeks. Nonserious adverse events occurred in 91.1% of patients, but only 0.4% were severe. Despite several study limitations, the authors concluded Treatment with lifestyle therapy and the 6-month swallowable gas-filled intragastric balloon system was safe and resulted in twice as much weight loss compared with a sham control, with high weight loss maintenance at 48 weeks. Study limitations include the short duration of randomized treatment (24 weeks) and limited long-term comparative data beyond balloon removal, which restricts conclusions regarding the durability of weight loss and longer-term safety outcomes.

Transoral Gastroplasty (TG)

For the treatment of obesity, TG has limited published literature, and the evidence is insufficient to provide conclusions on its safety and efficacy. Well-designed studies with long-term follow-up are needed, to measure the durability of the observed weight loss. In particular, the stability of the gastric sutures' procedure remains unproven, given the lack of long-term data.

Transoral Outlet Reduction (TORe)

Although preliminary results showing promising feasibility, safety, and short-term efficacy being demonstrated in case series (Jirapinyo 2013 [RESTORe trial]; Thompson 2013; Kumar 2014), longer-term durability of the procedure still needs to be proven in larger studies.

Jirapinyo et al (2020) conducted a retrospective review of prospectively collected data on RYGB patients who underwent TORe for weight regain or inadequate weight loss to assess long-term (5 year) efficacy. A total of 331 RYGB patients, with a mean BMI of 40±9 kg/m^2, underwent 342 TORe procedures. On follow-up, patients experienced a %TWL of 8.5 ± 8.5%, 6.9 ± 10.1%, and 8.8 ± 12.5% at 1, 3, and 5 years, respectively. At 5 years after TORe, nearly all patients had cessation of weight gain with the majority experiencing and maintaining clinically significant weight loss. Pre-TORe GJA size was 23.4 ± 6.0 mm, which decreased to 8.4 ± 1.6 mm after TORe. There were no severe or fatal AEs, with moderate AEs occurring in 11 out of 342 cases. The study was limited by a single site, retrospective design without a control group, one third of the patient received adjunctive therapy after the initial TORe, and technique variations over the years. The authors concluded that TORe appears to be safe, effective, and durable at treating weight regain after RYGB.

Valats et al (2024) conducted a prospective, multicenter, simple blind, randomized study evaluating the percentage of excess weight loss (%EWL) at 12 months following TORe in adults with weight recurrence after Roux-en-Y gastric bypass (RYGB). The final analysis included 50 subjects (25 per group), with a mean BMI of 40.6 kg/m². At 12 months, the TORe group demonstrated a significantly higher %EWL compared with the Sham group (p = 0.002), with a large effect size (Cohen's d = 0.91). No significant between-group differences were observed in the improvement of obesity-related comorbidities (diabetes, dyslipidemia) or quality-of-life measures at 12 months. Adverse events

occurred more frequently in the TORe group (20% procedural-related events). Three adverse events were classified as serious, including two gastro-jejunal anastomosis perforations in the TORe group, which led to premature termination of the study.

Routine Liver Biopsy in Conjunction with Bariatric Surgery

The impact on patient health outcomes has not been well-established, and there is insufficient clinical evidence to support routine liver biopsy in patients undergoing bariatric surgery.

Barajas-Gamboa et al (2025) performed a retrospective analysis of the Metabolic and Bariatric Surgery Accreditation and Quality Improvement Program (MBSAQIP) database from 2020 to 2022 of patients undergoing primary Roux-en-Y gastric bypass or sleeve gastrectomy with or without concomitant liver biopsy. Of the 511,981 patients, 30,819 (6.02%) underwent concomitant liver biopsy. The authors concluded that after adjusting for patient factors, the analysis demonstrates that concomitant liver biopsy during bariatric surgery does not independently increase the risk of major complications (Clavien-Dindo grade III and IV), readmission, or mortality. However, it is associated with statistically significant increases in both postoperative bleeding and transfusion requirements, though not with reoperation rates. When balancing the potential benefits of early liver disease diagnosis against risks, concomitant liver biopsy remains a reasonable option for appropriately selected patients undergoing bariatric surgery, provided clinicians are prepared for increased bleeding-related complications and blood product utilization. Careful patient selection, pre-operative optimization, and availability of blood products are essential considerations when planning concomitant liver biopsy.

Hiatal Hernia Repair in Conjunction with Bariatric Surgery

There is limited evidence regarding whether repair of hiatal hernias at the time of bariatric surgery improves outcomes after surgery; it consists primarily of cohort studies comparing outcomes for patients who had a hiatal hernia and underwent repair during bariatric surgery with patients without a hiatal hernia (Santonicola 2014; Gulkarov 2008).

Chen et al (2021) published a systematic review of 18 studies that evaluated outcomes after hiatal hernia repair plus sleeve gastrectomy (SG) in obese patients (N=937). Results demonstrated that patients who underwent hiatal hernia repair during SG had significant reductions in BMI, and the risk of GERD symptoms and esophagitis. Hiatal hernia repair during SG was superior to SG alone for GERD remission, but not de novo GERD.

PROFESSIONAL GUIDELINE(S)

Adults

The 2022 American Society for Metabolic and Bariatric Surgery (ASMBS) position statement on the impact of metabolic and bariatric surgery on nonalcoholic steatohepatitis concluded that metabolic and bariatric surgery has a positive impact on nonalcoholic fatty liver disease (NAFLD) and nonalcoholic steatohepatitis (NASH) either with or without fibrosis (Mazzini 2022). Although RCTs are needed to determine whether MBS should be considered as a frontline therapy for NAFLD and NASH, metabolic and bariatric surgery should be considered for patients with severe obesity.

In 2022, the ASMBS and International Federation for the Surgery of Obesity and Metabolic Disorders (IFSO) produced a joint statement on the current available scientific information on metabolic and bariatric surgery and its indications (Eisenberg 2022). Long-term data, published in the decades following the 1991 NIH Consensus Statement, consistently demonstrates the safety, efficacy, and durability of MBS in the treatment of clinically severe obesity. With significant improvement of metabolic disease, decreases in overall mortality, and superior weight loss outcomes compared with nonoperative treatment, the joint statement indicates:

- MBS is recommended for individuals with BMI >35 kg/m^2, regardless of presence, absence, or severity of comorbidities.
- MBS is recommended in patients with T2D and BMI >30 kg/m^2.
- MBS should be considered in individuals with BMI of 30 - 34.9 kg/m^2 who do not achieve substantial or durable weight loss or co-morbidity improvement using nonsurgical methods.
- Obesity definitions using BMI thresholds do not apply similarly to all populations. Clinical obesity in the Asian population is recognized in individuals with BMI >25kg/m^2. Access to MBS should not be denied solely based on traditional BMI risk zones.
- There is no upper patient-age limit to MBS. Older individuals who could benefit from MBS should be considered for surgery after careful assessment of co-morbidities and frailty.
- Children and adolescents with BMI >120% of the 95th percentile and a major co-morbidity, or a BMI >140% of the 95th percentile, should be considered for MBS after evaluation by a multidisciplinary team in a specialty center.
- MBS is an effective treatment of clinically severe obesity in patients who need other specialty surgery, such as joint arthroplasty, abdominal wall hernia repair, or organ transplantation.

The 2024 American Diabetes Association Standards of Medical Care in Diabetes sets forth recommendations for the treatment diabetes, including Section 8, which discusses metabolic surgery (ADAPPC 2024). Citing that a substantial body of evidence has demonstrated that metabolic surgery has beneficial effects on type 2 diabetes irrespective of pre-surgical BMI, including achieving superior glycemic management, reduction of cardiovascular risk and obesity, the ADAPPC recommends:

- Consider metabolic surgery as a weight and glycemic management approach in people with diabetes with BMI ≥30.0 kg/m^2 (or ≥27.5 kg/m^2 in Asian American individuals) who are otherwise good surgical candidates (grade A.)
- People being considered for metabolic surgery should be evaluated for comorbid psychological conditions and social and situational circumstances that have the potential to interfere with surgery outcomes (grade B).
- In people who undergo metabolic surgery, routinely screen for psychosocial and behavioral health changes, and refer to a qualified behavioral health professional as needed (grade C).
- Metabolic surgery should be performed in high-volume centers with interprofessional teams knowledgeable about and experienced in managing obesity, diabetes, and gastrointestinal

surgery (grade E).

Single-Anastomosis Duodeno-Ileal Bypass with Sleeve Gastrectomy (SADI-S)

The ASMBS endorses SADI-S as a modification of the classic Roux-en-Y duodenal switch (DS), an already-endorsed metabolic/bariatric procedure (Kallies 2020). The ASMBS states that it is reasonable to consider the SADI-S could be considered for endorsement with less available published peer-reviewed data than would be required for an entirely novel surgical procedure for which no predicate procedure exists. Based on additional publications the ASMBS concludes that SADI-S provides for similar outcomes to those reported after classic DS.

SADI-S was initially endorsed by the IFSO in 2020 (Brown 2021) and re-affirmed in 2023 (Ponce de Leon-Ballesteros 2024). Based on an updated systematic review of current evidence on SADI-S/SADS, the IFSO made the following recommendations:

- SADI-S/SADS is a safe and reproducible procedure with low rates of early and late complications. Also, it seems that primary procedures provide better outcomes in comparison to revisional procedures.
- SADI-S/SADS yields significant and sustained weight loss over a medium- to long-term period (5 years). However, there is a lack of data beyond the 6-year mark.
- SADI-S/SADS shows significant and sustained improvement in controlling type 2 diabetes mellitus (T2DM) in the medium term.
- To enhance the quality of evidence, the IFSO encourages participation in national and international registries, publication of long-term follow-up studies, and randomized controlled trials (RCTs).

In 2016, the National Institute for Health and Care Excellence (NICE) issued an interventional procedures guidance on single-anastomosis duodeno-ileal bypass with sleeve gastrectomy for treating morbid obesity. Based on six case series and zero randomized trials, the committee commented that there is potential for serious metabolic complication after the procedure and there may be a need for revision procedures. Evidence on efficacy is limited in both quality and quantity. NICE recommends that this procedure should only be used with special arrangements for clinical governance, consent and audit or research; patient selection should be done by a multidisciplinary team experienced in managing morbid obesity; treatment should be done by surgeons with specific training in the procedure, in centers with expertise in the treatment of morbid obesity.

Adults - Endoscopic Bariatric and Metabolic Therapies (EBMTs)

In 2024, the IFSO Bariatric Endoscopy Committee endorsed ESG as an effective and valuable intervention for managing obesity based on a comprehensive systematic review and meta-analysis of 44 articles (n=15,714 patients) (Abu Dayyeh 2024). The committee concluded that ESG is particularly beneficial for patients with class I and II obesity, as well as for those with class III obesity who are not suitable candidates for traditional MBS. This minimally invasive procedure not only achieves significant weight loss outcomes in the short and mid-terms but also maintains a favorable safety profile, as evidenced by a low incidence of serious adverse events.

In 2024, Jirapinyo and colleagues authored a joint guideline from the American Society for Gastrointestinal Endoscopy (ASGE) and the European Society of Gastrointestinal Endoscopy (ESGE) on primary endoscopic bariatric and metabolic therapies (EBMTs). Conditional recommendations (very low to moderate certainty) were made for lifestyle modification plus the use of intra-gastric balloons, aspiration therapy, duodenal-jejunal bypass liner, and endoscopic gastric remodeling (EGR) devices (e.g., Overstitch Endoscopic Suturing System) in adults with a BMI ≥30 kg/m², or a BMI of 27.0–29.9 kg/m² with at least one obesity-related comorbidity. Based on limited evidence, transpyloric shuttle and duodenal mucosal resurfacing (DMR) are recommended only in the context of a clinical trial.

In 2024, NICE recommended endoscopic sleeve gastroplasty as an option to treat obesity in adults. Reporting that evidence supports safety in the short and long term, and efficacy when combined with lifestyle changes for people with a body mass index (BMI) over 30 kg/m^2.

In 2013, NICE recommended that duodenal-jejunal bypass sleeve for managing obesity should only be used in the context of research given the limited quality and quality of evidence on safety and efficacy.

Children and Adolescents

In 2023, the American Academy of Pediatrics (AAP) published their first evidence-based clinical practice guideline for the evaluation and treatment of children and adolescents (ages 2 to 18 years) with obesity (Hampl 2023). The recommendations are based on evidence from RCTs, comparative effectiveness trials, high-quality longitudinal and epidemiologic studies gathered in a systematic review process described in their methodology. The AAP's recommendation related to bariatric surgery is: "Pediatricians and other pediatric health care providers should offer referral for adolescents 13 years and older with severe obesity (BMI ≥ 120% of the 95th percentile for age and sex) for evaluation for metabolic and bariatric surgery to local or regional comprehensive multidisciplinary pediatric metabolic and bariatric surgery center)."

In 2022, the ASMBS and International Federation for the Surgery of Obesity and Metabolic Disorders (IFSO) produced a joint statement on the current available scientific information on metabolic and bariatric surgery and its indications, stating MBS is safe and produces durable weight loss and improvement in comorbid conditions (Eisenberg 2022).

In 2019, the AAP published a report outlining the current evidence regarding adolescent bariatric surgery for adolescent metabolic and bariatric surgery that reflected the 2018 American Society for Metabolic and Bariatric Surgery (ASMBS) recommendations (Armstrong 2019). The AAP report noted that generally accepted contraindications to bariatric surgery included: "a medically correctable cause of obesity, untreated or poorly controlled substance abuse, concurrent or planned pregnancy, current eating disorder, or inability to adhere to postoperative recommendations and mandatory lifestyle changes."

In 2018, the American Society for Metabolic and Bariatric Surgery (ASMBS) Pediatric Committee updated its evidence-based guidelines published in 2012 (Pratt 2018). Based on an increased body of evidence the committee stated that metabolic and bariatric surgery (MBS) with vertical sleeve gastrectomy (VSG) and RYGB can be considered both safe and effective treatments for adolescents

with a BMI of 35 kg/m^2 or 120% of the 95th percentile with a co-morbidity or BMI ≥40 kg/m^2 or 140% of the 95th percentile without a comorbidity (whichever is lower). With limited data the committee indicated that adjustable gastric banding and biliopancreatic diversion with or without duodenal switch is less desirable and should be reserved for adults in most cases. Endoscopic bariatric therapies (e.g., intragastric balloons, vagal stimulation, gastric aspiration) are not currently FDA for under 18 years of age. Studies on long-term durability and physiological consequences are needed.

In 2017, the Endocrine Society's clinical practice guideline on pediatric obesity suggested that bariatric surgery be considered only for adolescents who have reached Tanner stage 4 or 5 and near-final adult height, have severe obesity (BMI ≥40 kg/m² or ≥35 kg/m² with serious comorbidities), and continue to have extreme obesity despite compliant lifestyle treatment, provided they also demonstrate psychological stability, the ability to follow healthy habits, and have access to an experienced pediatric bariatric surgery center capable of long-term metabolic and psychosocial follow-up (Styne 2017).

Intragastric Space Occupying Mechanisms

The American Society for Metabolic and Bariatric Surgery (ASMBS) published a position statement on intragastric balloon therapy which was endorsed by the Society of American Gastrointestinal and Endoscopic Surgeons (Ali 2016). Based on current evidence, intragastric balloon (IGB) therapy is FDA approved as an endoscopic, temporary (maximum 6 months) tool for the management of obesity, and further review will evaluate the impact of diet, lifestyle changes, and pharmacotherapy during and after balloon removal. Overall, the data suggests that the intragastric balloon is an effective tool for weight loss. Most of its effect was observed in the first 3 months after insertion, during which patients usually lost greater than 12 kilograms. At removal, or 6 months after insertion, studies, including randomized controlled trials, have suggested that the expected %EWL is about 24%. Early postoperative tolerance challenges can be significant but can be controlled with pharmacotherapy in the majority of patients, thereby minimizing voluntary balloon removals.

Hiatal Hernia Repair in Conjunction with Bariatric Surgery

In 2018, the ASMBS and the American Hernia Society published a consensus guideline on bariatric surgery and hernia surgery concluding that combined hernia repair and metabolic/bariatric surgery may be safe and associated with good short-term outcomes and low risk of infection (Menzo 2018).

Routine Liver Biopsy in Conjunction with Bariatric Surgery

American guidelines do not endorse routine liver biopsies with abdominal surgeries.

In 2023, the American Association for the Study of Liver Diseases (AASLD) published a practice guideline on the clinical assessment and management of nonalcoholic fatty liver disease, citing NAFLD is closely linked to and often precedes the development of metabolic abnormalities such as insulin resistance, dyslipidemia, central obesity, and hypertension (Rinella 2023). Statements within the guidance include:

- Liver biopsy should be considered when there is diagnostic uncertainty, competing or

concomitant possible diagnoses (e.g., autoimmune hepatitis, iron overload); or when there is persistent elevation (>6 month) in liver chemistries.

- General population-based screening for NAFLD is not advised.
- High-risk individuals (e.g., with T2DM, medically complicated obesity, family history of cirrhosis, or more than mild alcohol consumption) should be screened for advanced fibrosis.
- Patients with NAFLD who are overweight or obese should be prescribed a diet that leads to a caloric deficit. When possible, diets with limited carbohydrates and saturated fat and enriched with high fiber and unsaturated fats (e.g., Mediterranean diet) should be encouraged due to their additional cardiovascular benefits.
- Patients with NAFLD should be strongly encouraged to increase their activity level to the extent possible. Individualized prescriptive exercise recommendations may increase sustainability and have benefits independent of weight loss.
- Bariatric surgery should be considered as a therapeutic option in patients who meet criteria for metabolic weight loss surgery, as it effectively resolves NAFLD or NASH in the majority of patients without cirrhosis and reduces mortality from CVD and malignancy.

REGULATORY STATUS

The U.S. Food and Drug Administration (FDA) regulates bariatric surgery and endoscopic bariatric devices as medical devices. All bariatric surgery and endoscopic bariatric devices require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2026 Apr 27]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most serious type of recalls. Available from: https://www.fda.gov/medical-devices/medical-device-safety/medical-device-recalls-and-early-alerts [accessed 2026 Apr 27]

Adjustable Gastric Bands

- LAP-BAND (BioEnterics/Allerga/ReShape): Premarket approval (PMA) 2001, with expanded indication in 2011 allowing use in adults with BMI ≥30 with a comorbidity.
- REALIZE Band (Ethicon Endo-Surgery): PMA approved in 2007 for adults with BMI ≥40 or ≥35 with a comorbidity.

Intragastric Balloons/Space-Occupying Devices

- ORBERA (Apollo): PMA approved in 2015 for adults with BMI 30–40 as a temporary implant requiring removal at 6 months.
- ReShape Integrated Dual Balloon (ReShape Medical): PMA approved in 2015 for adults with BMI 30–40 as a temporary (remove at 6 months).

- Obalon Balloon System (Obalon): PMA approved in 2016 for adults with BMI 30–40 as a temporary implant.
- Allurion/ Elipse Swallowable Balloon (Allurion): FDA-approved in February 2026.
- TransPyloric Shuttle (TPS) (BAROnova): PMA approved in 2019 for BMI 35–40 or 30–34.9 with a comorbidity, indicated for up to 12 months of treatment.

Endoluminal Suturing/Tissue Approximation

- OverStitch (Apollo Endosurgery): 510(k)-cleared endoscopic suturing system for tissue approximation/ligation in the GI tract.
- StomaphyX (EndoGastric Solutions): 510(k)-cleared device in 2008 for trans-oral tissue approximation/ligation in the GI tract.

Not Approved for U.S. Marketing

- EndoBarrier (GI Dynamics): Not FDA-approved for commercial use in the U.S.
- TOGA System (Satiety): Not FDA-approved for U.S. marketing.
- AspireAssist (Aspire Bariatrics): PMA approved in 2016, but withdrawn from the U.S. market effective April 8, 2022, for business, not safety/effectiveness, reasons.

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
0813T (E/I)	Esophagogastroduodenoscopy, flexible, transoral, with volume adjustment of intragastric bariatric balloon
43290 (E/I)	Esophagogastroduodenoscopy, flexible, transoral; with deployment of intragastric bariatric balloon
43291 (E/I)	Esophagogastroduodenoscopy, flexible, transoral; with removal of intragastric bariatric balloon(s)
43644	Laparoscopy, surgical, gastric restrictive procedure; with gastric bypass and Roux-en-Y gastroenterostomy (roux limb 150 cm or less)
43645	with gastric bypass and small intestine reconstruction to limit absorption
43770	Laparoscopy, surgical, gastric restrictive procedure; placement of adjustable gastric restrictive device (e.g., gastric band and subcutaneous port components)

Code	Description
43771	revision of adjustable gastric restrictive device component only
43772	removal of adjustable gastric restrictive device component only
43773	removal and replacement of adjustable gastric restrictive device component only
43774	removal of adjustable gastric restrictive device and subcutaneous port components
43775	Laparoscopy, surgical, gastric restrictive procedure; longitudinal gastrectomy (i.e., sleeve gastrectomy)
43842	Gastric restrictive procedure, without gastric bypass, for morbid obesity; vertical-banded gastroplasty
43843	other than vertical-banded gastroplasty
43845	Gastric restrictive procedure with partial gastrectomy, pylorus-preserving duodenoileostomy and ileoileostomy (50 to 100 cm common channel) to limit absorption (biliopancreatic diversion with duodenal switch)
43846	Gastric restrictive procedure, with gastric bypass for morbid obesity; with short limb (150 cm or less) Roux-en-Y gastroenterostomy
43847	with small intestine reconstruction to limit absorption
43848	Revision, open, of gastric restrictive procedure for morbid obesity, other than adjustable gastric restrictive device (separate procedure)
43860	Revision of gastrojejunal anastomosis (gastrojejunostomy) with reconstruction, with or without partial gastrectomy or intestine resection; without vagotomy
43865	Revision of gastrojejunal anastomosis (gastrojejunostomy) with reconstruction, with or without partial gastrectomy or intestine resection; with vagotomy
43886	Gastric restrictive procedure, open; revision of subcutaneous port component only
43887	removal of subcutaneous port component only
43888	removal and replacement of subcutaneous port component only
43889 (E/I)	Gastric restrictive procedure, transoral, endoscopic sleeve gastroplasty (ESG), including argon plasma coagulation, when performed (Effective date 01/01/26)
47000 (*NMN)	Biopsy of liver, needle; percutaneous (*NMN when billed with an ICD-10 code listed below unless criteria under concomitant procedures is met.)
47001 (*NMN)	Biopsy of liver, needle; when done for indicated purpose at time of other major procedure (List separately in addition to code for primary procedure) (*NMN when billed with an ICD-10 code listed below unless criteria under

Code	Description
	concomitant procedures is met.)
47100 (*NMN)	Biopsy of liver, wedge (*NMN when billed with an ICD-10 code listed below unless criteria under concomitant procedures is met.)
47379 (*NMN)	Unlisted laparoscopic procedure, liver (*NMN when billed with an ICD-10 code listed below.)

HCPCS Codes

Code	Description
C9785 (E/I)	Endoscopic outlet reduction, gastric pouch application, with endoscopy and intraluminal tube insertion, if performed, including all system and tissue anchoring components
S2083	Adjustment of gastric band diameter via subcutaneous port by injection or aspiration of saline

ICD10 Codes

Code	Description
E66.0	Obesity due to excess calories
E66.01	Morbid (severe) obesity due to excess calories
E66.09	Other obesity due to excess calories
E66.2	Morbid (severe) obesity with alveolar hypoventilation
E66.3	Overweight
E66.811	Obesity, class 1
E66.812	Obesity, class 2
E66.813	Obesity, class 3
E66.89	Other obesity not elsewhere classified
E66.9	Obesity, unspecified
K91.0 - K91.32	Postprocedural complications and disorders of digestive system (code range)
K95.01- K95.09	Complications of gastric band procedure (code range)
K95.81- K95.89	Complications of other bariatric procedure (code range)
Z68.35-	Body mass index (BMI), 35.0-70 or greater, adult (code range)

Code	Description
Z68.45

Committee Approval Dates

New:08/90

Revised:12/94, 11/98, 09/99, 06/00, 10/03, 07/04, 02/05, 02/06, 04/07, 08/07, 03/08, 03/09, 01/10, 03/10, 03/11, 03/12, 03/13, 11/13 (regulatory requirement effective 9/25/13), 03/14,

07/14, 03/15, 03/16, 09/16, 03/18, 03/19, 5/21, 1/23, 3/23, 7/23. 3/24, 7/24, 3/25, 11/25 **Reviewed**:12/92, 10/95, 10/96, 11/97, 09/00, 01/03, 01/07, 03/17, 3/20, 3/21, 3/22, 7/26	
Date	**Summary of Changes**
06/16/26	• Code edit to add CPT 43889 to the policy after its erroneous removal.
1/1/2026	• Transitioned Bariatric Surgery policy, 1370/20.000061 to Lifetime Healthcare Companies policy template.
7/1/2023 *No change to effective date of policy	• Under Bariatric Surgical Procedures section removed statement about CDPHP network facilities as CMS no longer manages Centers of Excellence for bariatric surgeries:
7/1/2023 *No change to effective date of policy	Under Exclusions section: • Clarified code C9785 • Added misc. codes 43659 and 43999
7/1/2023 *No change to effective date of policy	• Under Medicare section added "or Gastric Reduction Duodenal Switch (BPD/GRDS)" as covered to be consistent with the Bariatric Surgery NCD. • Under Exclusions added Endoscopic sleeve gastroplasty and updated Gastric balloon device misc. code 43999 to codes 43290 and 43291. • Under Exclusions, added Apollo ESG and Natural Orifice Transluminal Endoscopic Surgery (NOTES) to the list of examples for Endoscopic oral-assisted bariatric surgery.
7/1/2023	• Added new code C9784 and C9785 to Procedure Codes section.
4/1/2023	• Removed termed vagus nerve blocking therapy codes (0312T-0317T) from Exclusions and replaced with existing code 64999. • Added Apollo Overstitch Device to Exclusions section.
1/1/23 *No change to effective date of policy	Under the Exclusions section, removed: • Gastric electrical stimulation (GES) or gastric pacing (43647, 43648, 43659, 43881, 43882, 43999, 64590, 64595, 95980, 95981, 95982) as this is listed in the Non-Covered Technologies policy.
9/1/2021	• Removed herniorrhaphy for an asymptomatic hiatal hernia from the exclusions section as it is considered incidental to the bariatric procedure

	whether it is symptomatic or asymptomatic. To reflect this change, this will be added to the Adjunct and Non-Standard Technology payment policy.

RESOURCE COORDINATION POLICY

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: BEHAVIORAL HEALTH ASSESSMENT & TRIAGE

POLICY EFFECTIVE DATE:	8/1/2023
Policy Control #:	**1370/20.000462**
Next Annual Review:	11/2026

DISCLAIMER

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgement when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice

DESCRIPTION

The CDPHP behavioral health department directly provides member triage and referral for behavioral health care services, including substance use, through a 24-hours-per-day/seven-days-per-week Behavioral Health Access Center (with normal business hours Monday through Friday, 8 a.m. to 6 p.m.). The access center is staffed by behavioral health professionals. Appropriately licensed, master's-prepared behavioral and social workers assist members with clinical determinations, urgent and emergent care, crisis calls, and referrals to facilities. Clinical intake specialists verify eligibility, confirm benefit information, elicit relevant clinical and psychosocial information, conduct clinical assessment (which includes evaluating for safety), and provide referrals for mental health and substance use treatment. Clinical intake specialists can also offer referrals to a broad range of community resources, including Legal Aid, National Alliance on Mental Illness, and Center for Independent Living. While adhering to HIPAA, family members may also receive outreach from the CDPHP behavioral health case manager to coordinate care for the member concerned. Industry-accepted protocols based on sound clinical evidence are used as the basis for all triage and referral decisions.

POLICY NAME: BEHAVIORAL HEALTH ASSESSMENT & TRIAGE

POSITION STATEMENT

Process utilized by the behavioral health department to systematically provide direction and assistance to the plan's members and providers in accessing behavioral health care services.

PROCEDURE	KEY POINTS
Calls managed by a clinical intake specialist	
1. A call is received on the toll-free *Behavioral Health Access Center* line (1-888-320-9584) where preliminary information is collected by the clinical intake specialist.	1. Information obtained includes: • The name of the caller and their relationship to the member for whom services are being requested. • The member's identification number, name, address, telephone number, and date of birth. • A brief description of the service(s) or information being requested.
2. The clinical intake specialist verifies eligibility.	2. If the member is not eligible, the clinical intake specialist informs the caller that eligibility is not in effect. *Note: clinical intake specialists can assist members who do not have active eligibility, including prospective members looking to join CDPHP or previous members with questions on past claims, authorizations, etc*. If eligibility is verified, the clinical intake specialist gives the caller a basic explanation of the benefit, including the following: • Member cost responsibility • Benefit limitations • If it requires authorization
3. If clinically appropriate based on caller's presentation and reported concerns, the clinical intake specialist conducts a clinical assessment to obtain necessary information to determine if additional steps are necessary to ensure safety and/or make a clinical recommendation on most appropriate level of care.	3. The purpose of the assessment is to collect a brief clinical picture of the member/caller's immediate need(s): • Suicidal or homicidal risk • Description of the problem • Description of any unusual symptoms • Description of prior treatment(s) • Perception of the current situation • Determination if there's substance use related crisis: • Triggers for potential SUD crisis: o Member says they "used too much" or used a large amount of a substance and they are scared for their acute

POLICY NAME: BEHAVIORAL HEALTH ASSESSMENT & TRIAGE

health/safety
- Member reports having trouble breathing or having breathing problems after using a substance or multiple substances
- Member with significantly slurred speech
- Member with significant difficulty maintaining train of thought during call
- Member is speaking incoherently or not making sense during the call
- Member indicates they are experiencing current withdrawal symptoms (have member elaborate on what symptoms they are experiencing e.g. nausea/vomiting/diarrhea, sweating, shaking, fast or irregular heart beat)
- Member makes any statement related to no longer wanting to live and/or wanting to overdose

If the member's responses to the assessment indicate imminent risk to harm self or others, the intake specialist keeps the member on the phone while another staff member calls a mobile crisis team and/or the police. The intake specialist remains on the line with the member until emergency services arrive and assure that the member is safe and receiving treatment.

If the member's response to the assessment indicate a substance use disorder diagnosis, the intake specialist can assist the member with referrals to OASAS for services both within and beyond their benefit (i.e. halfway houses). The intake specialist will also encourage self-referral and early entry into treatment.

If the member's responses to the assessment require advanced clinical judgment, the clinical intake specialist consults with behavioral health/HARP outpatient care manager. If the caller can contract for safety, the intake specialist transfers the caller to the behavioral health case manager. The care manager then follows below procedure, titled "Calls managed by a behavioral health/HARP outpatient care manager."

4. The caller gives information indicating no clinical judgment is necessary in making the triage and referral decision.	4. The clinical intake specialist facilitates a routine referral.
5. Members are given the opportunity to choose from several providers, including those OASAS providers for substance use disorder, within the CDPHP network, whenever possible.	5. Members are given the opportunity to make their own appointments for all behavioral health specialties, including substance use disorder, with providers once they are given the appropriate referral and identifying information.
6. For referrals to outpatient providers, the clinical intake specialist asks if the caller has any specific requests or preferences.	6. The clinical intake specialist will utilize Find-A-Doc, as well as internal knowledge and resources, to locate a provider(s) that matches the caller's preferences. If the caller is a new subscriber with CDPHP who is requesting authorization for their current out-of-network provider, the clinical intake specialist will provide caller with information regarding transition of care, based on CDPHP policy, and authorize if appropriate. If caller is requesting an out of network provider without applicable transition of care or out-of-network benefits, clinical intake specialist educates caller on their benefits and explains the member's right to request out-of-network coverage.
7. The clinical intake specialist gives the caller the names of providers depending on availability.	7. The intake specialist suggests to the caller to sign a *Permission to Exchange Information* for their primary care physician during their first session with their chosen provider. It is explained that the purpose of this disclosure is to coordinate treatment with their primary care physician.
8. Member needs directions to a provider's office.	8. The clinical intake specialist can assist by using a map application on the Internet: • Mapquest <www.mapquest.com> • Google Maps <https://maps.google.com/>
9. The clinical intake specialist completes the documentation in Facets before taking the next call.	
Calls managed by a behavioral health/HARP Outpatient care manager	
1. A member's incoming call is immediately transferred to the behavioral health/HARP outpatient care manager.	1. The following information is collected unless the urgency of the situation necessitates an abbreviated assessment:

	• Presenting problem/precipitating event. • Other relevant medical, behavioral health, or social/environmental history. • An informal assessment of mental status of the identified patient. (If the identified patient is not the caller, relevant questions can be asked of the caller.) • Further risk assessment including danger to self or others. This assessment is not intended to substitute for a face-to-face diagnostic evaluation. • The behavioral health/HARP outpatient care manager does not assign a diagnosis. • The behavioral health/HARP outpatient care manager collects only the information necessary to apply the medical necessity criteria and make a referral to an appropriate provider or facility-based outpatient program.
2. Referrals may be made to an outpatient practitioner or facility-based program, when appropriate.	2. The behavioral health/HARP outpatient care manager gives the caller the name of the nearest and/or most appropriate outpatient practitioner or facility-based program. An alternate can be offered, if available, when the member does not wish to use the nearest program.
3. Member needs directions to the facility-based outpatient program.	3. The behavioral health/HARP outpatient care manager assist by using a map application on the Internet through Mapquest <www.mapquest.com> or Google Maps <https://maps.google.com/>.
4. The behavioral health/HARP outpatient care manager documents his/her assessment and disposition in Salesforce	
5. The behavioral health manager, in coordination with the behavioral health medical director, is responsible for the clinical oversight of all triage and referral decisions	

POLICY CONSIDERATIONS

The appropriate level of care is determined by applying the medical necessity criteria as stated below.

Mental Health

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: BEHAVIORAL HEALTH ASSESSMENT & TRIAGE

InterQual provides nationally recognized, evidence-based criteria for various levels of mental health care, specific to member age. InterQual also provides an evidence base on common psychiatric treatment modalities including electro-convulsive therapy (ECT), transcranial magnetic stimulation (TMS) and further, new and existing technologies being used in the treatment of mental health conditions have coverage criteria outlined in CDPHP policy. See policy, *Experimental, Investigation and Non-Standard Treatment/Clinical Trials, 1370/20.000152.*

When the recommended level of care or service is not a covered benefit/not available through CDPHP (i.e., residential mental health treatment accessed through agencies licensed by the New York State Office of Mental Health or the New York State Office for People with Developmental Disabilities), the clinical intake specialist will educate and refer the member to the appropriate state agency.

In order to release any personal health information to anyone aside from the member, written authorization is required after they turn 14 years old.

Substance Use Disorders and Substance Use

The New York State Office of Addiction Services and Supports (OASAS), in partnership with The National Center on Addiction and Substance Abuse (CASA Columbia), has designed, built, and tested a web-based tool that aids health plans and substance-use treatment providers in determining the best level of care for a client with a substance use disorder. This tool is named the LOCADTR 3.0, which stands for Level of Care for Alcohol and Drug Treatment Referral.

CDPHP utilizes LOCADTR 3.0 for guiding decision making regarding the appropriate level of care for a member.

- The LOCADTR 3.0 is meant to ensure that all individuals in need of treatment for a substance use disorder have access to care and are placed in the setting closest to the client's community that provides a safe and effective setting for treatment.
- The data collected through the LOCADTR 3.0 is analyzed by NYS OASAS to assess provider and system level performance, inform needs assessments, and inform the relationship between level-of-care determinations and client outcomes. All personal health information collected will be protected and never redisclosed.
- Level of care (e.g., outpatient clinic, inpatient rehabilitation, residential care, etc.) is determined by a variety of factors, including:
    - Assessment of the client's need for crisis or detoxification services (for instance, determining possible medical complications from withdrawal);
    - Risk factors (such as the presence of severe medical and psychiatric conditions); and
    - Resources available to the client (for example, a social or family network supportive of recovery goals).

In order to release any personal health information to anyone aside from the member, written authorization is required after they turn 14 years old.

Adoption of the Protocols and Yearly Updates

The ***Behavioral Health Committee*** reviews all behavioral-health medical necessity and placement criteria protocols annually. This committee includes both community mental health/alcoholism/substance use providers and internal CDPHP mental health/alcoholism/substance use professionals. Suggestions from behavioral health are brought to the CDPHP Quality Management Committee (QMC), and approval

to continue the criteria is sought.

The protocol review focuses on two dimensions: intensity of service and severity of illness. CDPHP always uses the most current version of all protocols. The InterQual behavioral health criteria is updated on a yearly basis. The LOCADTR 3.0 has a "periodic" revision schedule.

Staff Qualifications

The ***clinical intake specialist*** conducts psychosocial and crisis assessment; intervention and stabilization services; triage to case management; evaluation of symptom acuity; and appropriate referral to network behavioral-health providers for next-day appointments and, when appropriate, to emergency services. The qualifications of the clinical intake specialist are an LPN degree or a bachelor's degree, strongly preferred in psychology or a related field, with at least two years of experience in a behavioral health-care environment required. Clinical intake specialists must also demonstrate clinical understanding of DSM 5 diagnoses, including mental health and substance use disorders, and have the ability to effectively manage members in crisis.

The ***Manager, Behavioral Health***oversees, monitors, and supports all activities of the clinical intake specialists, including call management, utilization management, and quality oversight of outpatient requests and authorizations; and serves as a bridge between the clinical intake unit, case managers, and care coordinators.

The ***behavioral health/HARP outpatient care manager*** makes triage and referral decisions requiring clinical judgment. The behavioral health case manager/social worker is a licensed professional who talks to members, assesses their clinical needs and urgency, and makes appropriate referrals. Based on the clinical and treatment needs of the member, the behavioral health case manager may maintain ongoing engagement with a member with identified goals related to their health care needs. The qualifications of the behavioral health case manager/social worker are as follows:

- RN, LMSW, LMHC, or LCSW with previous mental health or substance use experience.
- Knowledgeable with diagnosis and procedural coding, InterQual and LOCADTR 3.0 guidelines, psychiatric medication management, hospital case management, and related mental health and substance abuse treatment.

The ***Manager of behavioral health*** reports to the VP Integrated Care Management, who is a licensed professional, and oversees the behavioral health access center and provides supervision to the clinical intake staff. The behavioral health clinical intake unit manager monitors the consistent application of protocol and adequacy of documentation. For routine calls, the manager ensures utilization of established guidelines to conduct telephonic assessments and information collection. The manager holds daily clinical review with staff to review requests for treatment, and guides all utilization management decisions as they relate to authorization and quality oversight of outpatient services, such as PROS, Home and Community Based Services, and out-of-network requests for care. The manager oversees and provides crisis-management-related training and education to clinical intake specialists, as well as to other departments in CDPHP when necessary and/or appropriate.

The care management/HARP care management managers and supervisor are licensed professionals who oversee the behavioral health case managers to ensure consistent application of protocol, delivery of clinical assessment, adequate engagement with members, and consistency and completeness of documentation.

POLICY NAME: BEHAVIORAL HEALTH ASSESSMENT & TRIAGE

The ***Supervisor of behavioral health utilization review*** is a licensed master's-level practitioner who oversees staff responsible for making medical-necessity determinations for inpatient, residential services, and partial hospitalization and intensive outpatient program services. This includes daily oversight via chart review to monitor adequacy of documentation, and assessment of inter-rater reliability on a quarterly basis. The manager reviews a random sampling of authorization requests, and triages cases to staff based on clinical background. Supervisor is also responsible for the triage of cases to a medical director for review and final determination. The supervisor facilitates clinical rounds where cases are presented by utilization review staff to the medical director for utilization management determination. The supervisor provides daily oversight to the staff in the selection process for these cases. The supervisor educates and trains staff on utilization management tools to ensure consistent application of protocol, including InterQual, LOCADTR, and company policies.

A licensed ***psychiatrist*** experienced in clinical risk management oversees triage and referral decisions and makes all clinical denial decisions. The qualifications of the psychiatrist is licensure to practice medicine in New York State, with board certification in psychiatry. A minimum of seven years post-residency practice experience is required, including significant exposure to practicing in a managed care environment and experience with critical review in clinical scenarios.

DESCRIPTION

Behavioral health home and community-based services (BH HCBS) provide opportunities for an individual with mental illness and/or substance-use disorder (SUD) to receive services in his/her own home or community through a person-centered plan of care that meets the individual's needs.

BH HCBS includes the following services:

Habilitation Services
These services are typically provided on a 1:1 basis and designed to assist an individual with a behavioral health diagnosis (i.e., SUD or mental health) in acquiring, retaining, and improving skills such as communication, self-help, domestic, self-care, socialization, fine and gross motor skills, mobility, personal adjustment, relationship development, use of community resources, and adaptive skills necessary to reside successfully in home and community-based settings. These services assist an individual with developing skills necessary for community living and, if applicable, to continue the process of recovery from an SUD disorder. Services include things such as: instruction in accessing transportation, shopping and performing other necessary activities of community and civic life including self-advocacy, locating housing, working with

landlords and roommates, and budgeting. Services are designed to enable individuals to fully integrate into the community and endure recovery, health, welfare, safety, and maximum independence of the individual.

Educational Support Services

These services are provided to assist an individual with a mental health or substance use disorder who wants to start or return to school or formal training with a goal of achieving skills necessary to obtain employment. Educational support services consist of special education and related services as defined in Sections (22) and (25) of the Individuals with Disabilities Education Improvement Act of 2004 (IDEA) (20 U.S.C. 1401 et seq.), to the extent to which they are not available under a program funded by IDEA or available for funding by the NYS Adult Career & Continuing Education Services Office of Vocational Rehabilitation (ACCES-VR).

Education support services may consist of general adult educational services such as applying for and attending community college, university, or other college level courses. Services may also include classes, vocational training, and tutoring to receive a Test Assessing Secondary Completion (TASC) diploma, as well as support to the individual to participate in an apprenticeship program. An individual authorized for educational support services must relate to an employment goal or skill development documented in the service plan. Education support services must be specific in the service plan as necessary to enable an individual to integrate more fully into the community and to ensure the health, welfare, and safety of the individual. Examples of these goals would include but are not limited to: tutoring or formal classes to obtain a TASC diploma, vocational training, apprenticeship program or formal classes to improve skills or knowledge in a chosen career, community college, university, or any college-level courses or classes.

Ongoing supported education is conducted after an individual is successfully admitted to an educational program. Ongoing follow-along support is available for an indefinite period as needed by an individual to maintain his/her status as a registered student.

Individual Employment Support Services

Pre-Vocational Services

These are time-limited, face-to-face services that prepare an individual for paid or unpaid employment. This service specifically provides learning and work experiences where the individual with mental health and/or disabling substance use disorder can develop general, non-job-task-specific strengths and soft skills that contribute to employability in competitive work environments as well as in the integrated community settings. Pre-vocational services occur over a defined period of time and with specific person-centered goals to be developed and achieved, as determined by the individual and his/her employment specialist and support team and ongoing person-centered planning process as identified in the individual's person-centered plan of care. Pre-vocational services provide supports to an individual who needs ongoing support to learn a new job and/or maintain a job in a competitive work environment or a self-employment arrangement. The outcome of this pre-vocational activity is documentation of the

individual's stated career objective and a career plan used to guide individual employment support.

Transitional Employment
This service is designed to strengthen an individual's work record and work skills toward the goal of achieving assisted or unassisted competitive employment at or above the minimum wage paid by the competitive sector employer. This service is provided, instead of individual supported employment, only when the individual specifically chooses this service and may only be provided by clubhouse, psychosocial club program certified provider, or recovery center. This service specifically provides learning and work experiences where the individual with behavioral health and/or substance use disorder can develop general, non-job, task-specific strengths and soft skills that contribute to employability in the competitive work environment in integrated community settings paying at or above minimum wage. The outcome of this activity is documentation of an individual's stated career objective and a career plan used to guide individual employment support.

Intensive Supported Employment (ISE)
These are services that assist an individual with mental health/substance use disorder to obtain and keep competitive employment. This service is based on the individual placement and support (IPS) model which is an evidence-based practice of supported employment. It consists of intensive supports that enable individuals for whom competitive employment at or above the minimum wage is unlikely, absent the provision of supports, and who, because of their clinical and functional needs, require supports to perform in a regular work setting. Individual employment support services are individualized, person-centered services providing supports to an individual who needs ongoing support to learn a new job and maintain a job in a competitive employment or self-employment arrangement. An individual in a competitive employment arrangement receiving individual employment support services is compensated at or above the minimum wage and receives not less than the customary wage and level of benefits paid by the employer for the same or similar work performed by individuals without disabilities. The outcome of this activity is documentation of an individual's stated career objective and a career plan used to guide individual employment support.

Ongoing Supported Employment
This service is provided after an individual successfully obtains and becomes oriented to competitive and integrated employment. Ongoing follow-along support is available for an indefinite period as needed by an individual to maintain his/her paid employment position. Individual employment support services are individualized, person-centered services providing supports to an individual who needs ongoing support to learn a new job and maintain a job in a competitive employment or self-employment arrangement. An individual in a competitive employment arrangement receiving individual employment support services is compensated at or above the minimum wage and receives no less than the customary wage and level of benefits paid by the employer for the same or similar work performed by individuals without disabilities. The outcome of this service is documentation of an individual's stated career

Home And Community Based Services For Children 1370/20.000503

POSITION STATEMENT

CDPHP does not provide coverage for behavioral health home and community-based services identified above except for HARP as outlined below.

POLICY CONSIDERATIONS

FOR HARP ONLY

HCBS services defined in this policy are available for a HARP enrollee 21 years of age or older when the eligibility assessment completed by the Health Home identifies eligibility for HCBS services. An enrollee may be eligible for Tier 1 (employment services, education support services, peer support services) or Tier 2 (the full array). If the enrollee is not enrolled in a Health Home, the enrollee will be referred to a Recovery Care Agency (RCA) for assessments and plan of care development only. After completion of the brief assessment for eligibility, the Health Home Care Manager (HHCM) or RCA meets with the enrollee, at a location, date, and time convenient to the enrollee and the enrollee's chosen participants for a person-centered discussion about individual goal(s), engagement in current services, goal achievement, and additional needs. The HHCM or RCA utilizes this information to work with the enrollee to create a plan of care (POC) that includes both a behavioral health and primary care contact, and uses a whole person oriented, person-centered planning approach with health education/health promotion services. The HCBS POC includes preventative services (e.g., annual physicals) and health education/promotion services, including nicotine replacement services. Regular medical necessity criteria does not apply. Enrollee does not require active symptoms to be eligible for services. Enrollee's preferences (enrollee is not required to identify specific procedure code or provider to request service) and the presence of functional impairment is enough to support need.

The HHCM or RCA submits the following documentation to CDPHP, requesting level of service determination:

- Completed eligibility assessment, including Tier eligibility determination
- All services enrollee is currently receiving
- Enrollee's recovery goals

- Specific HCBS recommendations

CDPHP reviews the submitted documentation for support of requested service(s). The enrollee's CDPHP file is reviewed to identify eligibility, duplication of services (i.e. ACT, PROS), member suitability for service(s) based on information that may not have been available to Health Home or RCA, evidence of member readiness, and regulatory requirements identified for the requested HCBS. CDPHP works with the Health Home or RCA to resolve any issues impeding approval of the Level of Service request. CDPHP provides a level of service determination identifying providers taking referrals for the approved service(s).

Upon receipt of the level of service determination, the HHCM or RCA assists the enrollee in selecting provider participating in the CDPHP HARP provider network for each approved HCBS service and submitting referrals.

The HCBS provider(s) contacts CDPHP and is given approval for up to three (3) visits over a 14 calendar day period for assessment, and to complete and submit the *Adult Behavioral Health Home and Community Based Services Prior Authorization/Concurrent Review* form, identifying the frequency, scope, and duration for each requested service, as well as defining goals that accurately reflect the enrollee's HCBS POC, with objectives that are result-oriented, measurable steps toward the overall goal that can be achieved within the requested period of services.

CDPHP reviews the submitted *Adult Behavioral Health Home and Community Based Services Prior Authorization/Concurrent Review* form for support of the requested service(s). The enrollee's CDPHP file is reviewed to identify eligibility, duplication of services (i.e. ACT, PROS), member suitability for service(s) based on information that may not have been available to HCBS provider, evidence of member readiness, and regulatory requirements identified for HCBS, working with the enrollee and HCBS provider to finalize the POC. When finalized, CDPHP enters an authorization to approve or deny requested service. Written notification, including frequency, scope, and duration for approvals is provided to the enrollee, HCBS provider, and Health Home or RCA.

Throughout the HCBS review process, the HHCM or RCA continues to update the POC, as appropriate. If additional HCBS needs are identified during the process, a new request for HCBS Level of Service Determination is submitted to CDPHP. The completed POC is submitted to CDPHP for approval within 90 days of completing the eligibility assessment. The POC is reviewed for compliance with CMS requirements. Final POC is shared with a case manager who works collaboratively with the CDPHP utilization review team and the Health Home CM, or RCA, to monitor approved services, verifying approved services are rendered appropriately regarding the frequency, scope, and duration.

The HHCM or RCA conducts a re-assessment of HCBS needs on an annual basis, or after a significant change in condition, such as an inpatient admission or loss of housing.

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: Behavioral Health Home and Community Based Services for Adults

Continued stay is provided when the enrollee makes measurable progress toward goals, or there is evidence that the service plan has been modified to address the barriers in treatment progression, or continuation of services is necessary to maintain progress already achieved and/or prevent deterioration. Continued stay can be requested by telephone, or by submitting an updated *Adult Behavioral Health Home and Community Based Services Prior Authorization/Concurrent Review* form.

Plan of care meetings involving the enrollee, Health Home or RCA, and HCBS provider(s) are conducted, at a location, date, and time convenient to the enrollee and the enrollee's chosen participants, to evaluate the plan of care and identify possible updates to the current plan of care. Enrollee specific requests made during these meetings, as well as requests agreed to by the team, are submitted to CDPHP for review. The enrollee is not required to provide a procedure code or request a specific provider for the requested service. CDPHP will identify procedure code corresponding to the requested service and provide the enrollee with names of providers available to provide the service.

Service specific criteria is identified below:

Rehabilitation Services

Habilitation Services
Admission/Eligibility

- Enrollee requires habilitation and onsite services that may include, but are not limited to: cognition (cognitive skills), functional status (ADLs), and recovery-oriented community support
- Providers who do not apply for both PSR and Habilitation are encouraged to apply for both services. Programs without a joint designation will not be allowed to serve individuals having both a PSR and Habilitation goal on their Plan of Care

Limitations/Exclusions

- The total number of Habilitation hours cannot exceed 500 in a calendar year. Time limited exception to this limit for enrollee transitioning from institution is permitted if prior authorized and found to be part of the cost-effective package of services provided to the enrollee compared to institutional care
- Benefit excluded if enrolled in: ACT

Education Support Services
Admission/Eligibility

- Enrollee who has been assessed to need education support services and clearly states interest in obtaining employment with the skills obtained

Limitations/Exclusions

- Hours for supported education are limited to no more than a total of 250 hours per year
- Documentation is maintained in the file of each individual receiving this service that the

service is not otherwise available under section 110 of the Rehabilitation Act of 1973 or the IDEA
- This service is accessible only if other appropriate state plan services are not available or appropriate
- Benefit excluded for enrollee enrolled in: ACT program

Individual Employment Support Services

Pre-Vocational Services
Admission/Eligibility
- Enrollee must have a clear desire to work in competitive employment

Limitations/Exclusions
- Total combined hours (for pre-vocational services and transitional supported employment) are limited to no more than a total of 250 hours and a duration of nine months of service in a calendar year
- For all employment supports services, documentation is maintained in the file of each enrollee receiving this service that the service is not available under a program funded under section 110 of the Rehabilitation Act of 1973 or the IDEA (20 U.S.C. 1401 et seq.). Federal financial participation is not claimed for incentive payments, subsidies, or unrelated vocational training expenses, such as the following:
  - Incentive payments made to an employer to encourage or subsidize the employer's participation in a supported employment program
  - Payments that are passed through to users of supported employment programs, **and**
  - Payments for training that is not directly related to an enrollee's supported employment program.
- When pre-vocational services are provided at a work site where persons are competitively employed, payment is made only for the adaptations, supervision, and training required by enrollee receiving services as a result of their disabilities but does not include payment for the supervisory activities rendered as a normal part of the business setting or work environment.
- Benefit excluded if enrolled in ACT or PROS program

Transitional Employment
Admission/Eligibility
- Enrollee must have made a clear decision to work in competitive employment in the community regardless of limited or unsuccessful work history, or present status of sobriety and/or abstinence
- The basic tenet of transitional employment is that enrollee is capable of working in competitive employment in the community even without prior training and enrollee interested in employment should be given the opportunity

Limitations/Exclusions

- Total combined hours for pre-vocational and transitional supported employment are limited to no more than a total of 250 hours and a duration of nine months of service in a calendar year
- Transitional Employment placements are part-time and time-limited, usually 15-20 hours/week from 6-9 months in duration
- Documentation is maintained in the file of each enrollee receiving this service that the service is not available under a program funded under section 110 of the Rehabilitation Act of 1973 or the IDEA (20 U.S.C. 1401 et seq.). Federal financial participation is not claimed for incentive payments, subsidies, or unrelated vocational training expenses, such as the following:
    - Incentive payments made to an employer to encourage or subsidize the employer's participation in a supported employment program
    - Payments that are passed through to users of the state VR supported employment programs, **and**
    - Payments for training that is not directly related to an individual's supported employment program
- When employment support services are provided in a competitive and integrated work site where persons without disabilities are employed, payment is made only for the adaptations, supervision, and training required by enrollee receiving services as a result of their disabilities and does not include payment for the supervisory activities rendered as a normal part of the business setting.
- Benefit excluded if enrolled in: ACT or PROS program

Intensive Supported Employment (ISE)
Admission/Eligibility

- Enrollee must make a clear decision to work in competitive employment in the community
- The basic tenet of ISE is that enrollee is capable of working in competitive employment in the community even without prior training and enrollee interested in employment should be given the opportunity.
- Ongoing level of care criteria including service duration, intensity and effectiveness will be reviewed by the HCBS care manager and/or CDPHP at least quarterly

Limitations/Exclusions

- 250 hours per calendar year
- For all employment supports services, documentation is maintained in the file of each individual receiving this service that the service is not available under a program funded under section 110 of the Rehabilitation Act of 1973 or the IDEA (20 U.S.C. 1401 et seq.). Federal financial participation is not claimed for incentive payments, subsidies, or unrelated vocational training expenses, such as the following:
    - Incentive payments made to an employer to encourage or subsidize the employer's participation in a supported employment program
    - Payments that are passed through to users of supported employment programs,

and

- Payments for training that is not directly related to an enrollee's supported employment program

- When employment support services are provided at a work site where persons without disabilities are employed, payment is made only for the adaptations, supervision, and training required by an enrollee receiving waiver services as a result of their disabilities but does not include payment for the supervisory activities rendered as a normal part of the business setting.
- Benefit excluded if enrolled in: ACT or PROS program

Ongoing Supported Employment

Admission/Eligibility

- Enrollee must make a clear goal to maintain employment in a competitive work environment in the community

Limitations/Exclusions

- 250 hours per calendar year
- For all employment supports services, documentation is maintained in the file of each individual receiving this service that the service is not available under a program funded under section 110 of the Rehabilitation Act of 1973 or the IDEA (20 U.S.C. 1401 et seq.). Federal financial participation is not claimed for incentive payments, subsidies, or unrelated vocational training expenses, such as the following:
  - Incentive payments made to an employer to encourage or subsidize the employer's participation in a supported employment program
  - Payments that are passed through to users of supported employment programs, **and**
  - Payments for training that is not directly related to an individual's supported employment program.
- When employment support services are provided at a work site where persons without disabilities are employed, payment is made only for the adaptations, supervision, and training required by an enrollee receiving services as a result of their disabilities but does not include payment for the supervisory activities rendered as a normal part of the business setting.
- Benefit excluded if enrolled in ACT or PROS program

PROCEDURE CODES

H2017, H0036, H0038, H2014

DESCRIPTION

Behavioral Health Community Oriented Recovery and Empowerment (CORE) services provide opportunities for an individual with mental illness and/or substance-use disorder (SUD) to receive person-centered, recovery oriented, mobile behavioral health supports that are intended to build skills and self-efficacy along with facilitating community participation and independence. CORE services must be offered in the setting and modality best suited to support an enrollee's goal acquisition including in the enrollee's home and other community-based locations during times and locations that are convenient for the individual. The scope and intensity of CORE services are based on the level of support needed to assist the individual in achieving their recovery goal(s) and sustaining recovery.

Psychosocial Rehabilitation (PSR)

Psychosocial Rehabilitation (PSR) is designed to assist an individual in improving their functional abilities to the greatest degree possible in settings where they live, work, learn, and socialize. Rehabilitation counseling, skill building, and psychoeducational interventions provided through PSR are used to support attainment of person-centered recovery goals and valued life roles. Approaches are intended to develop skills to overcome barriers caused by an individual's

behavioral health disorder and promote independence and full community participation.

Community Psychiatric Support and Treatment (CPST)

Community Psychiatric Support and Treatment (CPST) includes goal-directed supports and solution-focused interventions with the intent to achieve person-centered goals and objectives. This is a multi-component service that consists of therapeutic interventions such as clinical counseling and therapy, which assist the individual in achieving stability and functional improvement. CPST addresses behavioral health barriers that impact daily living, finances, housing, education, employment, personal recovery and/or resilience, family and interpersonal relationships, and community participation.

CPST is designed to provide mobile treatment services to individuals who have difficulty engaging in site-based programs, or who have not been previously engaged in services, including those who had only partially benefited from traditional treatment. CPST allows for delivery of services within a variety of permissible of-site settings including, but not limited to, community locations where the individual lives, works, learns, and/or socializes.

Empowerment Services – Peer Supports

Empowerment Services – Peer Support (Peer Support) are non-clinical, peer-delivered services with focus on rehabilitation, recovery, and resilience. They are designed to promote skills for coping with and managing behavioral health symptoms while facilitating the utilization of natural supports and community resources.

Peer Support must include the identified goals or objectives in the individual's ISP, with interventions tailored to the individual. These goals should promote utilization of natural supports and community services, supporting the person's recovery and enhancing the quality of their personal and family life. The intentional, goal-directed activities provided by this service emphasize the opportunity for peers to model skills and strategies necessary for recovery, thereby developing the individual's skills and self-efficacy. These services are provided through the perspective of a shared personal experience of recovery, enhancing the individual's sense of empowerment and hope.

Family Support and Training

Family Support and Training (FST) offers instruction, emotional support, and skill building necessary to facilitate engagement and active participation of the family in the individual's recovery process. The FST practitioner partners with families through a person-centered or person-directed, recovery oriented, trauma-informed approach.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: Behavioral Health Community Oriented Recovery and Empowerment (CORE) Services

Family is defined as the individual's family of choice. This may include persons who live with or provide support to a person, such as a parent, spouse, significant other, children, relatives, foster family, in-laws, or others defined as family by the individual receiving services. Family does not include individuals who are employed to care for the individual receiving services.

RELATED POLICIES/DOCUMENTS

Home and Community Based Services for Adults, 1370/20.000489
Home and Community Based Services for Children, 1370/20.000503

POSITION STATEMENT

CORE services defined in this policy are available for a HARP enrollee 21 years of age or older who receive a recommendation from a Licensed Practioner of the Healing Arts (LPHA). Enrollees may learn about and be referred to CORE services through multiple sources including: the MCO, care manager, inpatient and outpatient clinicians, primary care practitioners, family and friends or provider outreach and education efforts. CORE providers must notify CDPHP within three (3) business days after the first date of initiating a new CORE service. CORE service initiation for new referrals will begin with intake and evaluation sessions, which must be completed within 30 days of the initial visit or the first five (5) visits, whichever occurs later. CORE service providers must submit a service initiation template and CDPHP will confirm there are no duplication of services. These services are not case management, personal care services, nor a replacement for custodial care receive services in his/her own home or community through a person-centered plan of care that meets the individual's needs. NYS has recommended CORE service unit ranges, intended to illustrate the scope of service and program design which may be exceeded when clinically appropriate.

POLICY CONSIDERATIONS

Psychosocial Rehabilitation (PSR)

Psychosocial Rehabilitation is provided individually and in groups. PSR includes the following components:

- Person-Centered Assessment, Recovery Planning, Documentation, and Collaboration: A person-centered planning process is used support the individual's recovery goal. This component includes but is not limited to:
    - Engaging the individual in shared decision making around service and recovery planning.
    - Regular assessment of progress toward goals and updating the ISP, as needed. The PSR practitioner may include record keeping exercises designed to support the individual in monitoring their progress. Staff may use a person-driven concurrent or collaborative documentation process to support this work; and,

  - Communicating with collaterals, including other providers, to ensure integrated, collaborative services and access to necessary supports/resources.
- Individual Psychoeducation and Skill Building: Interventions designed to develop or improve personal coping strategies, prevent crises, and promote recovery. These interventions are tailored to the individual's goal and are adapted to where the individual lives, works, learns, and socializes. Providers may utilize the Wellness Self-Management (WSM) approach. This component includes but is not limited to:
  - Mental health and addiction psychoeducation.
  - Coping skills and stress reduction/management skills training.
  - Problem-solving skills training.
  - Medication education and self-management skills training; and
  - Crisis prevention planning.
- Rehabilitation Counseling: Individualized, goal-driven interventions that facilitate, promote, and improve functioning in living, working, learning, and social environments. Rehabilitation Counseling is used to help the individual choose, get, and keep valued life roles. This component includes but is not limited to:
  - Identification of strengths and resources which may aid the individual in achieving recovery; supporting the individual's personal development, work, and academic performance, and functioning in social and family environments through teaching skills/strategies to ameliorate the effect of behavioral health symptoms.
  - Resource and support coordination to help an individual identify, assess, develop, and secure available supports to ensure their success and satisfaction in their stated rehabilitation goals. This may include working with the individual to use their existing supports, finding new supports, and modifying available supports to meet their needs.
  - Identification of personal, environmental, and behavioral health barriers that may impede the development of skills necessary for functioning in work or school, with peers, and with friends and family.
  - Develop, strengthen, and support the individual's independent community living skills and community participation through self-advocacy and system navigation; promoting access to necessary rehabilitative, medical, social, academic, and other services and supports.
  - Instruction in accessing and using community resources such as transportation, translation, and communication assistance; for example, helping to secure TTY services, language services, or other adaptive equipment needs.
  - Instruction and skill building to increase the individual's capacity to independently manage their own financial resources, including public benefits and entitlements, scholarships and financial aid, work incentives, and earned income.

Community Psychiatric Support and Treatment (CPST)

CPST may be provided to an individual and their family of choice. Components may be

delivered to the family with or without the individual present if the intervention is for the benefit of the individual and with the individual's informed consent. Interventions should be evidence-based. CPST includes the following components:

- Person-Centered Assessment, Service Planning, Documentation, and Collaboration
- Individual and Family Psychotherapy and Counseling
- Integrated Co-Occurring Disorder Treatment
- Crisis Prevention
- Intensive Rehabilitation Counseling

CPST may also include the following optional components:

- Health Monitoring
- Medication Treatment

Empowerment Services – Peer Support

Peer Support is provided individually. It includes the following components

- Person-Centered Recovery Planning, Documentation, and Collaboration
- Advocacy Support
- Activation and Engagement in Recovery
- Community Participation
- Transitional Support
- Pre-Crisis and Crisis Support

Family Support and Training

Family Support and Training is provided individually and in groups. It may be provided to an individual and their family of choice. Components may be delivered to the family with or without the individual present if the intervention is for the benefit of the individual and with the individual's informed consent. Components may also be delivered to the individual without the family present, as appropriate. FST includes the following components:

- Person-Centered Recovery Planning, Documentation, and Collaboration
- Education
- Skill Building and Support

EXCLUSIONS/LIMITATIONS

Psychosocial Rehabilitation (PSR)

- Services may complement, not duplicate, services aimed at supporting enrollee to achieve employment-related goals in his/her plan of care.
- PSR must be provided by staff who meet the minimum criteria for unlicensed behavioral health staff and who have completed the required trainings within timeframes specified in the NYS Staff Training Memo. The Staff Training Memo includes enhanced training for staff delivering PSR to individuals with employment and education-related goals.

  - Unlicensed behavioral health staff must receive clinical supervision by a qualified supervisor.
  - Psychosocial Rehabilitation does not include task-specific job training (i.e., job coaching).
  - There is a 1-12 recommended daily unit range for individual PSR.
  - PSR groups may last from 15 minutes to 1 hour and may be delivered on the same day as a 1:1 PSR session with an individual. There is a 1-4 recommended daily unit range for group PSR.
  - 1:1 PSR services may be delivered in any combination on a single day, including PSR with Employment Focus and PSR with an Educational Focus, up to a total of 12 units per day.
  - Benefit excluded if enrolled in: ACT and PROS
- **PSR with Education Focus**
  - Services may complement, not duplicate, services aimed at supporting enrollee to achieve employment-related goals in his/her plan of care.
  - Benefit excluded if enrolled in: ACT, PROS and BH Home and Community Based Education Support Service.
- **PSR with Employment Focus**
  - Services may complement, not duplicate, services aimed at supporting enrollee to achieve employment-related goals in his/her plan of care.
  - Benefit excluded if enrolled in: ACT, PROS, and BH Home and Community Based Pre-vocational, Transitional Employment,Intensive Supported Employment Service, or Ongoing Support Employment Service.

Community Psychiatric Support and Treatment (CPST)

- Community treatment for eligible enrollee can continue if needed, within the limits, based on the enrollee's needs.
- Intent of service is to eventually transfer care to a site-based setting.
- Services comparable to CORE CPST are available through OMH Clinic. Enrollees may access non-duplicative services through CORE CPST and Article 31 OMH Outpatient Clinic in a single month for the following purposes:
  - Access to a psychiatric prescriber (e.g. psychiatric assessment/evaluation, medication management, health monitoring) if the CPST provider does not have a prescriber. Receiving psychotherapy through CPST and the Article 31 Clinic is duplicative. Medication management and supporting activities through the Article 31 Clinic are duplicative if the CPST provider has a prescriber on staff.
  - Transition from CPST to clinic-based services, allowing for a warm-handoff during the clinic pre-admission process (3 sessions).
- The CPST provider should maintain communication with the prescriber to ensure integrated treatment/care.
- CPST may be delivered by the following qualified staff, within their scope of practice. Qualified staff must complete required trainings within timeframes specific in the NYS

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: Behavioral Health Community Oriented Recovery and Empowerment (CORE) Services

Staff Training Memo.

Component	Qualified Staff Who May Deliver
Person-Centered Assessment, Service Planning, Documentation, and Collaboration; Intensive Rehabilitation Counseling	Psychiatrist, Psychiatric Nurse Practitioner, Psychologist, Social Worker, Mental Health Counselor, Marriage and Family Counselor, Psychoanalyst, Creative Arts Therapist, Certified Rehabilitation Counselor
Individual and Family Psychotherapy; Integrated Co-Occurring Disorder Treatment; Crisis Prevention	Psychiatrist, Psychiatric Nurse Practitioner, Psychologist, Social Worker, Mental Health Counselor, Marriage and Family Counselor, Psychoanalyst, Creative Arts Therapist
Health Monitoring	Psychiatrist, Physician, Nurse Practitioner, Psychiatric Nurse Practitioner, Physician's Assistant, RN, LPN
Medication Treatment	Psychiatrist, Psychiatric Nurse Practitioner
Student Interns may also deliver components appropriate to their educational program. See Provider Types in Appendix for details on degrees, licenses, and/or permits required for each of the above qualified staff.	

- CPST group services are not allowed.
- There is a recommended daily unit range of 1-6 for CPST
- Benefit excluded if enrolled in: ACT, PROS, CDT, or PHP.

Empowerment Services – Peer Support

- Enrollee receiving an OASAS state plan peer service may also receive CORE Peer Supports. The providers should work together to ensure there is no service duplication. The allowable peer services shall complement, not duplicate one another.
    - Note: Peer services while an enrollee is incarcerated or institutionalized are not Medicaid reimbursable. Time spent on the phone with enrollee is not Medicaid reimbursable. The cost of admission to an event (i.e., sports event or concert) is not Medicaid reimbursable. Advocacy for community improvement (not specific to the Medicaid eligible enrollee) is not Medicaid reimbursable.
- Peer Support must be provided by a Certified Peer who has completed the required trainings within timeframes specified in the NYS Staff Training Memo.
- Certified Peers must receive clinical supervision by a qualified supervisor.

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: Behavioral Health Community Oriented Recovery and Empowerment (CORE) Services

- Empowerment Peer support groups services are not allowed as this service should be rendered under the PSR benefit.
- There is a 1-16 recommended daily unit range for Empowerment Services- Peer Support.
- Benefit excluded if enrolled in: ACT program.

Family Support and Training

- FST must be provided by staff who meet the minimum criteria for unlicensed behavioral health staff and who have completed the required trainings within timeframes specified in the NYS Staff Training Memo.
- Unlicensed behavioral health staff must have access to clinical supervision by a qualified supervisor.
- This service is provided only at the request of the individual. All FST must be included in the individual's ISP and for the benefit of the Medicaid covered participant.
- There is a 1-12 recommended daily unity range for individual FST.
- Groups may last from 15 minutes to 90 minutes and may be delivered on a same day as single-family session. Groups are made up of 2-3 HARP members' families. While FST is only delivered at the request of the individual, the individual is not required to attend group sessions. There is no limit on how many family members may participate per HARP member. There us a 1-6 recommended daily unit range for group FST.
- Benefit excluded if enrolled in: ACT or PROS program

For all CORE services, the Individual Service Plan (ISP) should be developed utilizing the recommended ranges for each service. The recommended unit range does not apply to an individual in crisis, although the crisis should be clearly documented.

These ranges may be exceeded when a short-term increase in intensity supports goal acquisition. Outside of crisis situations, the decision to exceed the recommended range by the CORE provider should only be made in consultation with their Clinical Supervisor, who should consider whether a higher level of care is needed. An example of when it might be appropriate to exceed the recommended range is an individual who is returning to school and requires Psychosocial Rehabilitation to take day-long college tours and attend college fairs.

CDPHP PRODUCT VARIATIONS

CDPHP, CDPHP UBI, & CDPHN:	CDPHP does not provide coverage for behavioral health community-oriented recovery and empowerment services identified above except for HARP as outlined below.

MEDICAL POLICY

Medical Policy Title	**Bioengineered Tissue Products for Wound Treatment and Surgical Interventions**
Policy Number	**7.01.35**
Current Effective Date	**September 1, 2026**
Next Review Date	**August 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service.
(Link to Product Disclaimer)

POLICY STATEMENT(S)

This policy does not address fibrin sealants (e.g., Tisseel) or repair of ocular defects.

I. The following bioengineered tissue products are considered **medically appropriate** for the listed indications, when criteria are met:

A. Diabetic Foot Ulcers (AlloPatch, Apligraf, AmnioBand Membrane, Biovance, Dermagraft, EpiCord, EpiFix, Grafix CORE, Grafix PRIME, Integra, Integra Dermal Regeneration Matrix (Omnigraft), Oasis Wound Matrix, TheraSkin) when meeting **ALL** of the following criteria:

1. The patient has adequate arterial blood supply as evidenced by ankle-brachial index (ABI) of 0.65 or greater in the limb being treated;
2. The patient is competent or has support system required to participate in follow-up care associated with treatment with a bioengineered tissue product;
3. Ulcers are full thickness, extend through the dermis but without tendon, muscle, capsule, or bone exposure, and of greater than three (3) weeks' duration for which standard wound therapy has failed;
4. Patient has adequate treatment of underlying disease process(es) contributing to the ulcer;
5. Ulcers are located on foot or toes and are free of infection, redness, drainage, underlying osteomyelitis, surrounding cellulitis, tunnels and tracts, eschar, or any necrotic material that would interfere with adherence of a bioengineered tissue product and wound healing;
6. Patient's current HbA1C does not exceed 12%; and
7. Absence of the following contraindications:
   a. Known hypersensitivity to bovine collagen, silicone, or chondroitin materials;
   b. Pregnancy;
   c. Clinically diagnosed infected wounds.

B. Venous Ulcers (Apligraf, AmnioBand, EpiFix, Oasis Wound Matrix, TheraSkin) when meeting

ALL of the following criteria:

1. The patient has adequate arterial blood supply as evidenced by ankle-brachial index (ABI) of 0.65 or greater in the limb being treated;
2. The patient is competent or has support system required to participate in follow-up care associated with treatment with a bioengineered tissue product;
3. Ulcers are partial or full thickness and have failed to respond to conservative measures of at least one (1) month duration that have, at a minimum, included regular dressing changes, debridement of necrotic tissue, and standard therapeutic compression. ("Failure to respond" is defined as increase in size or depth or no change in size or depth with no sign or indication that improvement is likely, such as granulation, epithelialization, or progress toward closing);
4. Patient has adequate treatment of the underlying disease process(es) contributing to the ulcer; and
5. Ulcers are free of infection, redness, drainage, underlying osteomyelitis, surrounding cellulitis, tunnels and tracts, eschar or any necrotic material that would interfere with adherence of a bioengineered tissue product and wound healing.

C. Breast Reconstruction (Alloderm, AlloMax/Cortiva, DermACELL AWM, DermaMatrix, FlexHD, GraftJacket, Surgimend)
   1. Breast reconstruction surgery following surgical mastectomy
      a. Evidence on acellular dermal matrix (ADM) in post-mastectomy expander/implant breast reconstruction is varied and conflicting. Surgeons should evaluate each clinical case individually and objectively determine the use of ADM.

D. Nasal Repairs (Alloderm)
   1. Septal repair, septal perforation repair, or reconstructive septorhinoplasty

E. Non-Primary Hernia Repair (Alloderm)
   1. When chronic infection contraindicates the use of mesh or other conventional repair

F. Parotidectomy (Alloderm)

G. Burns
   1. Integra Dermal Regeneration Matrix (Omnigraft) when meeting **ALL** of the following criteria:
      a. Insufficient autograft is available at the time of burn excision; **and**
      b. When used for **ANY** of the following indications:
         i. post excisional treatment of a full thickness or deep partial thickness burn;
         ii. for repair of scar contractures secondary to third-degree burns;

2. Biobrane
    a. When used as a temporary covering for clean, debrided superficial and partial thickness burns and donor sites;
3. Epicel
    a. deep dermal or full thickness burns over greater than 30% of the body;
4. TransCyte
    a. When used for temporary covering of a surgically excised deep partial or full thickness burn wound as a covering prior to autografting.

II. After initial treatment has been completed, reinitiated treatment on the same wound site less than one (1) year after successful treatment is considered treatment failure and **not medically appropriate**.

III. **ALL** other bioengineered tissue products are considered **investigational** for **ANY** indication.

RELATED POLICIES

Corporate Medical Policy

10.01.01 Breast Reconstruction Surgery

11.01.03 Experimental or Investigational Services

POLICY GUIDELINE(S)

I. Specific products should only be used in accordance with US Food and Drug Administration (FDA) product approval and when the above policy criteria are met.

II. If a product is not FDA approved for the indication for which it is being used (i.e.., "off label" use), documentation of a shared decision-making process and informed consent is required.

III. The FDA requests prompt reporting of adverse effects associated with bioengineered tissue products through MedWatch, the FDA Safety Information and Adverse Event Reporting Program.

IV. If a wound has not responded to standard of care by achieving a 50% or better wound reduction after four weeks of standard of care, a single application of a bioengineered tissue product was thought to be all that was required to affect wound healing in wounds likely to be improved by this treatment. Based on clinical input from wound specialists, refractory wounds rarely heal with one graft application and may require additional graft applications, no more frequently than once per week, until the wound heals. Re-application of a product is appropriate only if there has been measurable response to the first application.

V. Treatment of venous stasis ulcers that extend above the malleoli is beyond the scope of practice of podiatrists.

DESCRIPTION

Bioengineered tissue products are cellular (contain living cells) or acellular (no biological component)

matrices that can be derived from human tissue (autologous or allogeneic), nonhuman tissue (xenographic), synthetic materials, or a composite of these materials. Manufacturing processes vary, but generally involve seeding selected cells onto a matrix, where they receive proteins and growth factors necessary for them to develop into the desired tissue. The tissue may then be used for a variety of procedures, including breast reconstruction, treatment of severe burns, and healing of diabetic and venous ulcers.

SUPPORTIVE LITERATURE

Diabetic Foot Ulcers (AlloPatch, Apligraf, AmnioBand Membrane, Biovance, Dermagraft, EpiCord, EpiFix, Grafix CORE, Grafix PRIME, Integra, Integra Dermal Regeneration Matrix (Omnigraft), Oasis Wound Matrix)

Tettelbach et al (2018) conducted a multicenter prospective randomized controlled comparative parallel study at 11 centers in the United States. The aim of this study was to determine the safety and effectiveness of dehydrated human umbilical cord allograft (EpiCord) compared with alginate wound dressings for the treatment of chronic, non-healing diabetic foot ulcers (DFU). Individuals with a confirmed diagnosis of Type 1 or Type 2 diabetes presenting with a 1 to 15 cm2 ulcer located below the ankle that had been persisting for at least 30 days were eligible for the 14-day study run-in phase. After 14 days of weekly debridement, moist wound therapy, and off-loading, those with ≤30% wound area reduction post-debridement (n = 155) were randomized in a 2:1 ratio to receive a weekly application of EpiCord (n = 101) or standardized therapy with alginate wound dressing, non-adherent silicone dressing, absorbent non-adhesive hydropolymer secondary dressing, and gauze bandage roll (n = 54). Study visits were conducted for 12 weeks. Data for randomized subjects meeting study inclusion criteria were included in an intent-to-treat (ITT) analysis. Additional analysis was conducted on a group of subjects (n = 134) who completed the study per protocol (PP) (EpiCord, n = 86, alginate, n = 48) and for those subjects receiving adequate debridement (EpiCord, n = 67, alginate, n = 40). ITT analysis showed that DFUs treated with EpiCord were more likely to heal within 12 weeks than those receiving alginate dressings, 71 of 101 (70%) vs 26 of 54 (48%) for EpiCord and alginate dressings, respectively, P = 0.0089. Healing rates at 12 weeks for subjects treated PP were 70 of 86 (81%) for EpiCord-treated and 26 of 48 (54%) for alginate-treated DFUs, P = 0.0013. For those DFUs that received adequate debridement (n = 107, ITT population), 64 of 67 (96%) of the EpiCord-treated ulcers healed completely within 12 weeks, compared with 26 of 40 (65%) of adequately debrided alginate-treated ulcers, P < 0.0001. Seventy-five subjects experienced at least one adverse event, with a total of 160 adverse events recorded. There were no adverse events related to either EpiCord or alginate dressings. The authors conclude these results demonstrate the safety and efficacy of EpiCord as a treatment for non-healing DFUs.

A review article (Zelen 2015a) addresses the use of human amnion/chorion membrane (dHACM) for lower extremity repair. The article states:

Although there is limited data available regarding most amniotic membrane-based products, there is substantial preclinical and clinical evidence supporting the rationale and effectiveness of dHACM allograft as a treatment modality. The rapidly growing body of evidence suggests that the properties inherent in dHACM promote tissue regeneration and healing, recruiting patients' own stem cells into

the wounded area. Randomized controlled trials evaluating dHACM now include more than 200 patients collectively and the results consistently show improved healing. Use of dHACM has been shown to be more clinically effective and cost-effective than other frequently used advanced wound care products. This cost-effectiveness results from dHACM showing higher healing rates and more rapid healing than other advanced wound care products. Cost-effectiveness is also enhanced through the availability of grafts of multiple sizes, which reduces wastage, and through ease of handling and storage for clinical use. Ongoing and future studies will further define and establish the value of amniotic membrane for chronic tissue repair and regeneration.

A small, industry-sponsored, non-blinded, RCT comparing the use of EpiFix (n=13) with SOC (moist wound therapy, n=12) for diabetic foot ulcers of at least four weeks' duration (Zelen 2013). EpiFix was applied every two weeks if the wound had not healed, with weekly dressing changes consisting of non-adherent dressing, moisture retentive dressing, and a compression dressing. Standard moist wound dressing was changed daily. After four weeks of treatment, EpiFix-treated wounds had reduced in size by a mean of 97.1%, compared with 32.0% for the SOC group. Healing rate (complete epithelialization of the open area of the wound) was 77% for EpiFix, compared with 0% for SOC. After six weeks of treatment, wounds were reduced by 98.4% with EpiFix treatment, compared with -1.8% for SOC. The healing rate was 92% with EpiFix, compared with 8% with standard treatment alone.

Treatment with EpiFix, Apligraf, or standard wound care was compared in a multicenter randomized, controlled study (Zelen2015b). Sixty patients with chronic lower extremity diabetic ulcers were randomized to treatment with Epifix (dehydrated human amniotic membrane), Apligraf (human skin allograft with living fibroblasts and keratinocytes), or standard wound care. Although the patient and site investigator could not be blinded due to differences in products, wound healing was verified by three independent physicians who evaluated photographic images. The median wound size was 2.0 cm^2 (range, 1.0-9.0), and the median duration of the index ulcer was 11 weeks (range, 5-54). After six weekly treatments, the mean percent wound area healed was 97.1% for EpiFix, 80.9% for Apligraf, and 27.7% for standard care; 95% of wounds had healed in the EpiFix group compared with 45% treated with Apligraf and 35% who received standard wound care ($p<0.003$). The estimated median time to wound closure, based on Kaplan-Meier analysis, was 13 days for EpiFix, compared with 49 days for both Apligraf and SOC ($p<0.001$).

In 2015, Kirsner et al reported an industry-sponsored observational study comparing the effectiveness of Apligraf and EpiFix for the treatment of diabetic foot ulcers in a real-world setting. Data were obtained from a wound care–specific database from 3000 wound care facilities. The database included 1458 diabetic ulcers treated for the first time in 2014 with Apligraf (n=994) or EpiFix (n=464). After study inclusion criteria, data were included on the treatment of 226 diabetic foot ulcers from 99 wound care centers. Foot wounds were included with size between 1 cm2 and 25 cm2, duration of one year or less, and wound reduction of 20% or less in the 14 days prior to treatment. Although wounds for the two groups were comparable at baseline, the rationale for using a particular product was not reported. There were 163 wounds treated with Apligraf (mean, 2.5 applications) and 63 treated with EpiFix (mean, 3.5 applications, p=0.003). By week 24, 72% of wounds treated with Apligraf and 47% of wounds treated with EpiFix had closed (p=0.01).

Treatment with Grafix or standard wound care was compared in a small, multi-centered RCT for diabetic foot ulcers (Lavery 2014). Although the results were positive, the sample size was small, with 50 treated with Grafix and 47 in the control group treated with SOC. The primary end point was complete wound closure by 12 weeks. Grafix patients who achieved full closure was 62% versus 21% in the control group receiving SOC. Ananian et al (2018) reported a prospective, randomized, single-blind study comparing the efficacy of Grafix with Dermagraft. The end result of this study was measured by wound closure and showed that Grafix (48.4% closure) is non-inferior to Dermagraft (38.7% closure).

AmnioBand was compared to SOC for treatment of non-healing diabetic foot ulcers in an industry-sponsored, multi-center study (DiDomenico 2016). Forty patients were randomized to SOC or SOC with AmnioBand for up to 12 weeks. Complete healing by six weeks was observed for 70% of wounds treated with SOC and AmnioBand versus 15% treated with SOC alone. At 12 weeks, complete healing was observed in 85% of the SOC and AmnioBand group versus 25% treated with SOC alone. Limitations of the study were small sample size, a drop-out rate of 9/40, and the wound area in the control group was larger than in the treatment group.

Smiell et al (2015) reported on an industry-sponsored, multicenter registry study of Biovance d-HAM for the treatment of various chronic wound types; about a third (n=47) were diabetic foot wounds. Of those treated, 28 ulcers had failed prior treatment with advanced biologic therapies. For all wound types, 41.6% closed within a mean time of 8 weeks and a mean of 2.4 amniotic membrane applications.

AlloPatch, which is a pliable human reticular, acellular dermis, was compared to SOC in the treatment of diabetic foot ulcers in an industry-sponsored, multicenter trial (Zelen 2017). The trial was powered to detect a 45% difference between groups in percentage healing at six weeks with 20 patients per group. Evaluation of the outcome measures was not blinded. At six weeks, 65% (13/20) of wounds treated with AlloPatch had healed, compared to 5% (1/20) in the SOC-alone group ($p<0.001$). After adjusting for wound area at baseline, the hazard ratio for healing was 168 (95% CI, 10 to 2704; $p<0.001$), indicating a lack of precision in the estimate. Per protocol, 10 patients in the SOC group and one in the AlloPatch group exited the study at six weeks because their wounds failed to reduce in area by at least 50%. According to ITT analysis with last observation carried forward, the percentage of wounds healed at 12 weeks was 80% in the AlloPatch group, compared to 20% in the SOC group. However, because there was a high (50%) withdrawal rate in the SOC group, this result has a high risk of bias.

Integra Dermal Regeneration Template*,* marketed as Omnigraft*,* randomized, controlled studies have been shown to improve healing of chronic, non-healing diabetic foot ulcers with the use of Omnigraft (Driver 2015). The Foot Ulcer New Dermal Replacement (FOUNDER) multicenter study on the use of Integra Dermal Regeneration Template for chronic, non-healing diabetic foot ulcers was conducted under an FDA-regulated investigational device exemption. A total of 307 patients with at least one chronic diabetic foot ulcer were randomized to treatment with the Integra Template or a control condition (0.9% sodium chloride gel). Treatment was given for 16 weeks or until wound closure. There was a modest increase in wound closure with the Integra Template (51% versus 32%) and a

shorter median time to closure (43 days versus 78 days). There was a strong correlation between investigator-assessed and computerized planimetry assessment of wound healing (r=0.97). Kaplan-Meier analysis showed the greatest difference between groups in wound closure up to 10 weeks, with diminishing differences after 10 weeks. Strengths of the study included adequate power to detect an increase in wound healing of 18%, which was considered to be clinically significant, as well as secondary outcomes of wound closure and time to wound closure by computerized planimetry and intention-to-treat (ITT) analysis.

The Oasis Wound Matrix (Cook Biotech) is a xenogeneic collagen scaffold derived from porcine small intestinal mucosa. Niezgoda et al (2005) compared healing rates at 12 weeks for full-thickness diabetic foot ulcers treated with the OASIS Wound Matrix (an acellular wound care product) to Regranex Gel. This industry sponsored, multicenter RCT was conducted at nine outpatient wound care clinics and involved 73 patients with at least one diabetic foot ulcer. Patients were randomized to receive either Oasis Wound Matrix (n=37) or Regranex Gel (n=36) and a secondary dressing. Wounds were cleansed and debrided, if needed, at a weekly visit. The maximum treatment period for each patient was 12 weeks. After 12 weeks, 18 (49%) Oasis-treated patients had complete wound closure, compared with 10 (28%) Regranex-treated patients. Oasis treatment met the noninferiority margin, but the study did not demonstrate that healing in the Oasis group was statistically superior (p=0.055). Post hoc subgroup analysis showed no significant difference in incidence of healing in patients with type 1 diabetes (33% versus 25%) but showed a significant improvement in patients with type 2 diabetes (63% versus 29%). There was also an increased healing of plantar ulcers in the Oasis group (52% versus 14%).

TheraSkin was reported in a small (n=23), industry-funded, randomized comparison of TheraSkin (human skin allograft with living fibroblasts and keratinocytes) to Dermagraft (human-derived fibroblasts cultured on mesh) for diabetic foot ulcers (Sanders 2014). Wound size at baseline ranged from 0.5 to 18.02 cm^2; the average wound size was about 5 cm^2 and was similar for the two groups (p=0.51). Grafts were applied according to the manufacturer's instructions over the first 12 weeks of the study until healing, with an average of 4.4 TheraSkin grafts (every two weeks) compared with 8.9 Dermagraft applications (every week). At week 12, complete wound healing was observed in 63.6% of ulcers treated with TheraSkin and 33.3% of ulcers treated with Dermagraft (p<0.049). At 20 weeks, complete wound healing was observed in 90.9% of the TheraSkin-treated ulcers, compared with 66.67% of the Dermagraft group (p=0.428).

Venous Ulcers (Apligraf, Oasis Wound Matrix)

Hankin et al (2012) explains venous leg ulcers (VLUs) are commonly associated with substantial disability, impaired quality of life, and high economic costs. Compression therapy, which has remained the standard care for VLUs over several decades, is often insufficient to heal VLUs in a timely manner. VLU-related treatment costs are directly related to time to achieve complete wound closure. Advanced wound care matrices (AWCMs) developed to stimulate wound healing may reduce VLU-related costs associated with delayed healing.

Mostow et al (2005) conducted a prospective, randomized, controlled multicenter trial to compare the effectiveness of Oasis wound matrix with compression vs compression alone in healing chronic leg

ulcers within 12 weeks. Participants included 120 patients with at least one (1) chronic leg ulcer, randomly assigned to receive either weekly topical treatment of Oasis plus compression therapy (n = 62) or compression therapy alone (n = 58). Ulcer size was determined at enrollment and weekly throughout the treatment. Healing was assessed weekly for up to 12 weeks. Recurrence after 6 months was recorded. The primary outcome measure was the proportion of ulcers healed in each group at 12 weeks. After 12 weeks of treatment, 55% of the wounds in the Oasis group were healed, as compared with 34% in the standard-care group (P = .0196). None of the healed patients treated with Oasis wound matrix and seen for the 6-month follow-up experienced ulcer recurrence. The authors concluded the study showed Oasis wound matrix, as an adjunct therapy, significantly improves healing of chronic leg ulcers over compression therapy alone.

A prospective, head-to-head, single site randomized clinical trial pilot study evaluated the effectiveness of two (2) biologically active grafts, TheraSkin and Apligraf, in conjunction with compression therapy (Towler 2018). The study was not industry-sponsored and was designed and conducted to assess differences in healing rates, adverse outcomes, and treatment costs. Although there were higher venous leg ulcer (VLU) healing rates with the TheraSkin cohort compared with the Apligraf cohort at both 12 weeks (93.3% vs 75.0%) and 20 weeks (93.3% vs 83.3%), these healing rate differences were not statistically significant. There was no statistically significant difference in the number of grafts required to achieve wound closure within limitations of the small sample size presented and there were no adverse outcomes. There was a statistically significant 42.2% decrease in cost for the appropriate graft sizes in the TheraSkin cohort ($2495.33/subject) compared with the Apligraf cohort ($4316.67/subject), even though the initial wound sizes were not significantly different between groups. This suggests that TheraSkin may provide equivalent or superior outcomes to Apligraf while reducing costs though the authors concluded that the use of either of these biologics in conjunction with compression therapy is a safe and effective way to treat VLUs.

Landsman et al (2011) published a study examining TheraSkin for safety and efficacy in the treatment of venous leg ulcers (VLUs) and diabetic foot ulcers (DFUs). The objective was to determine if TheraSkin could serve as a safe and effective alternative to bioengineered skin substitutes such as Apligraf and Dermagraft. The authors conducted a retrospective study of 214 consecutive patients seen at the Inova Wound Center (Mt Vernon, Virginia), with either a DFU or a VLU. After excluding patients who did not meet the study criteria, the final eligible cohort consisted of 188 subjects, with 134 VLUs and 54 DFUs. Multivariate logistic regression was used to evaluate the relationship between baseline wound size and the proportion of healed wounds after 12 and 20 weeks from initial allograft application. The authors found that by the 12th week, DFUs closed 60.38% of the time and VLUs closed 60.77% of the time. After 20 weeks, the number of closed DFUs increased to 74.1% and the number of VLUs increased to 74.6%. The mean wound size in the DFU group was 6.2 cm (2) (±11.8) and 11.8 cm (2) (±22.5) in the VLU group. The mean number of TheraSkin allografts required ranged from 1 to 8, with an average of 2.03 (±1.47) at the 12-week point and an average of 3.23 (±2.77) at the 20-week point. Multivariate logistic regression was used to calculate the odds of wound healing by week 12 and week 20 in each group. The authors also analyzed adverse events and found TheraSkin to be noncontributory to any adverse events, verifying the safety of TheraSkin in this study population. The authors concluded, TheraSkin has been shown

to be highly effective for the treatment of both VLUs and DFUs with an acceptable safety profile.

A randomized, controlled, multicenter clinical trial was conducted to evaluate the efficacy of dehydrated human amnion/chorion membrane (EpiFix) allograft as an adjunct to multilayer compression therapy for the treatment of non-healing full-thickness venous leg ulcers (Bianchi 2018). The authors randomly assigned 128 subjects initially though only 109 subjects finished the trial. They received EpiFix and multilayer compression (n = 52) or dressings and multilayer compression therapy alone (n = 57). Patients were recruited from 15 centers around the United States and were followed up for 16 weeks. The primary end point of the study was defined as time to complete ulcer healing. Participants receiving weekly application of EpiFix and compression were significantly more likely to experience complete wound healing than those receiving standard wound care and compression (60% versus 35% at 12 weeks, P = 0·0128, and 71% versus 44% at 16 weeks, P = 0·0065). A Kaplan-Meier analysis was performed to compare the time-to-healing performance with or without EpiFix, showing a significantly improved time to healing using the allograft (log-rank P = 0·0110). Cox regression analysis showed that subjects treated with EpiFix had a significantly higher probability of complete healing within 12 weeks (HR: 2·26, 95% confidence interval 1·25-4·10, P = 0·01) versus without EpiFix. The authors concluded these results confirm the advantage of EpiFix allograft as an adjunct to multilayer compression therapy for the treatment of non-healing, full-thickness venous leg ulcers.

Bianchi et al (2019) published further analysis on the previously mentioned cohort of patients in a follow-up study. The purpose of this study is to report intention-to-treat (ITT) results on all 128 randomized subjects and assess if both ITT and per-protocol (PP) data analyses arrive at the same conclusion of the efficacy of EpiFix as a treatment for VLU. Rates of healing for the ITT and PP populations were, respectively, 50% and 60% for those receiving EpiFix and 31% and 35% for those in the standard care cohort. Within both ITT and PP analyses, these differences were statistically significant; P = 0.0473, ITT and P = 0.0128, PP. The Kaplan-Meier plot of time to heal within 12 weeks for the ITT and PP populations demonstrated a superior wound-healing trajectory for EpiFix compared with VLUs treated with standard care alone. The authors concluded that these data provide clinicians and health policymakers with an additional level of assurance regarding the effectiveness of EpiFix.

An open label randomized controlled trial including patients with chronic venous leg ulcers was conducted at eight (8) wound care centers across the United States (Serena 2022). This industry sponsored trial evaluated the safety and effectiveness of weekly and biweekly applications of dehydrated human amnion and chorion allograft (dHACA) (AmnioBand Membrane; MTF Biologics) plus standard of care compared to standard of care alone on chronic venous leg ulcers. The primary endpoint was the proportion of healed ulcers at 12 weeks. Secondary endpoints included the proportion of ulcers achieving 40 percent closure at 4 weeks and the incidence of adverse events. Among 101 patients screened for eligibility, 60 were eligible and enrolled. At 12 weeks, significantly more venous leg ulcers healed in the two dHACA-treated groups (75 percent) than in the standard-of-care group (30 percent) (p = 0.001) even after adjustment for wound area (p = 0.002), with an odds ratio of 8.7 (95 percent CI, 2.2 to 33.6). There were no significant differences in the proportion of wounds with percentage area reduction greater than or equal to 40 percent at 4 weeks among all

groups. The adverse event rate was 63.5 percent. Among the 38 adverse events, none were graft or procedure related, and all were resolved with appropriate treatment. The authors concluded, dHACA and standard of care, either applied weekly or biweekly, significantly healed more venous leg ulcers than standard of care alone, suggesting that the use of aseptically processed dHACA (AmnioBand Membrane; MTF Biologics) is advantageous and a safe and effective treatment option in the healing of chronic venous leg ulcers.

Breast Reconstruction (Alloderm, AlloMax/Cortiva, DermACELL AWM, DermaMatrix, FlexHD, GraftJacket, Surgimend)

A prospective study was completed which evaluated limited submuscular direct-to-implant technique utilizing AlloMax where only the upper few centimeters of the implant is covered by the pectoralis, whereas the majority of the implant including the middle and lower poles are covered by acellular dermal matrix (Brichacek 2017). Nineteen consecutive patients with 37 reconstructed breasts were studied and followed up to six (6) months postoperatively. Average age was 50 years, average BMI was 24.3, ptosis ranged from grade 0-III, and average cup size was B (range, A-DDD). Early minor complications included one (1) seroma, three (3) minor postoperative hematomas managed conservatively, and 3 minor wound healing problems. Three breasts experienced mastectomy skin flap necrosis and were managed with local excision. There were no cases of postoperative infection, red breast syndrome, grade III/IV capsular contractures, or implant loss. A single patient complained of animation postoperatively. One patient desired fat grafting for rippling. The limited submuscular direct-to-implant technique utilizing AlloMax appears to be safe with a low complication rate at 6 months. This technique minimizes the action of the pectoralis on the implant, reducing animation deformities but still providing muscle coverage of the upper limit of the implant. Visible rippling is reduced, and a vascularized bed remains for fat grafting of the upper pole if required.

Zheng et al (2025) reported a single, academic institution's experience with two (2) ADM brands in breast reconstruction and provides data on clinical and financial outcomes. A retrospective chart review of patients who underwent two-staged breast reconstruction with Cortiva Allograft Dermis was matched with a cohort who received AlloDerm RTU. Comparison of clinical outcomes, such as complications and revision surgeries, in addition to a cost analysis was completed. The study cohort included 24 patients who received Cortiva and 24 patients who received AlloDerm. There were no statistical differences in demographics or breast-specific characteristics between the cohorts. Major complications were not statistically increased with Cortiva use [Hazard Ratio 1.78 (0.421-7.66)], but the rate of revision following second-stage reconstruction trended toward significance with Cortiva use [3.41 (0.99-11.80), p=0.05]. The material base cost and total cost following surgeries were lower for Cortiva (44% of the AlloDerm costs), but the incremental costs did not display significant difference secondary to comparable complication and revision rates. The authors concluded that the use of Cortiva Allograft Dermis was shown to have a decreased cost in base material and total cost associated with surgery while also displaying comparable clinical outcomes and complication rate.

A single-blinded randomized controlled trial comparing Cortiva with AlloDerm in prepectoral and subpectoral immediate prosthetic breast reconstruction was performed at two (2) academic hospitals from March of 2017 to December of 2021 (Keane 2024). Reconstructions were direct to implant (DTI)

or tissue expander (TE). Primary outcome was reconstructive failure, defined as TE explantation before planned further reconstruction, or explantation of DTI reconstructions before 3 months postoperatively. Secondary outcomes were additional complications, patient-reported outcomes (PROs), and cost. There were 302 patients including: 151 AlloDerm (280 breasts), 151 Cortiva (277 breasts). The majority of reconstructions in both cohorts consisted of TE (62% versus 38% DTI), smooth device (68% versus 32% textured), and prepectoral (80% versus 20% subpectoral). Reconstructive failure was no different between ADMs (AlloDerm 9.3% versus Cortiva 8.3%; P = 0.68). There were no additional differences in any complications or PROs between ADMs. Seromas occurred in 7.6% of Cortiva but 12% of AlloDerm cases, in which the odds of seroma formation were two-fold higher (odds ratio, 1.93 [95% CI, 1.01 to 3.67]; P = 0.047). AlloDerm variable cost was 10% to 15% more than Cortiva, and there were no additional cost differences. The authors concluded, when assessing safety, clinical performance, PROs, and cost, Cortiva is noninferior to AlloDerm in immediate prosthetic breast reconstruction, and may be less expensive, with lower risk of seroma formation.

Kaplan HY and Rysin R (2025) published a retrospective study evaluating a patient cohort that underwent primary or revisional breast reconstruction (DTI) utilizing DermaCell, from Jan 2017 to Jan 2024 by a single surgeon. A total of 230 consecutive patients, 410 breasts, and 801 DermaCell sheets were evaluated. All were DTI breast reconstructions. Complication rate was described per breast. A total of 92 cases of complication occurred (22.4%). Rippling was seen in 18 breasts (4.39%), skin ischemia in 21 breasts (5.12%), hematoma in 5 (1.21%), and seroma in 9 (2.19%). Seventeen breasts experienced capsular contraction. In the nonirradiated group, capsular contracture (CC), Baker grade 3 to 4, was seen in 4 breasts (1.11%), with 9 (18%) in the irradiated group. The postoperative follow-up period was 18 months (range: 6-84 months). BREAST-Q satisfaction with the breast increased by a mean of 10.45. Satisfaction with the implant was 6.61 out of 8. The authors concluded that DermaCell ADM offers a safe and reliable option and is an important component in prepectoral breast reconstruction, contributing to better results, an improved complication profile, and patient satisfaction.

Glynou SP et al (2024) conducted a network meta-analysis to compare outcomes of different ADMs that are commonly used during implant-based reconstruction (IBR). A total of 51 studies were captured by the search, of which 27 were included in the network meta-analysis. Alloderm was the most used ADM (54%), followed by Porcine (17%), Bovine (11%), Dermacell (11%), and FlexHD (7%). The mean follow-up was 27.8 months. The complication rates varied. Porcine ADMs had the highest rate of seroma formation (10.3%) and of hematoma formation (2.7%). AlloDerm FD had the highest rate of wound dehiscence (3.1%). Implant failure was highest in AlloDerm FD ADMs (11.8%), followed by Porcine ADMs (11.2%). Infections were most common in Porcine (11.2%) and AlloDerm FD ADMs (11.0%). Capsular contracture was rare across all ADM types, with no significant differences observed. In the network meta-analysis (NMA), AlloDerm FD showed significantly higher risks of infection, explantation, and wound dehiscence compared to AlloDerm RTU. The overall complication profiles of ADMs used in IBR are similar, except for the higher risks associated with AlloDerm FD compared to RTU. These findings suggest that the choice of ADM may not significantly impact overall outcomes, except in specific cases like AlloDerm FD. Further high-quality, long-term,

double-arm studies are necessary to confirm comparative profile of specific ADM types and to account for potential confounding variables through multivariable regression analysis.

Davison SP et al (2024) conducted a prospective, patient-blind study of patients undergoing bilateral nipple and/or skin-sparing mastectomies with either tissue expander or silicone implant insertion between 2019 and 2022 were selected for this study. The study design used patients as their own controls between two (2) products randomly assigned to the left or right breast. Outcomes between the products included average time for drain removal, infection rate, seroma rate, and incorporation rates. The prospective clinical data of 55 patients (110 breasts) were recorded for 90 days. There were no significant differences between drain removal time, average drain output, or seroma aspiration amount. A higher percentage of seromas was recorded in the breasts with AlloDerm (30.91%) compared with breasts containing DermACELL (14.55%, P < .05), and a statistically significant difference between the incorporation rates of AlloDerm (93.4%) and DermACELL (99.8%, P < .05) was observed. Irrespective of patient demographic disparities, both products had a 94.55% success rate for reconstruction outcomes. AlloDerm was determined to have a higher incidence of seroma as a postoperative complication and a trend to lower incorporation.

The Breast Reconstruction Evaluation of Acellular Dermal Matrix as a Sling Trial (BREASTrial) is a blinded, randomized trial comparing the outcomes of tissue expander breast reconstruction using AlloDerm or DermaMatrix (Mendenhall 2023). In this final stage of the trial, outcomes 3 months to 2 years after definitive reconstruction are reported along with patient satisfaction data. A randomized trial was conducted to compare complication rates between groups of patients who underwent reconstruction with AlloDerm and DermaMatrix. Regression models were used to analyze the impact of matrix type, age, chemotherapy, radiation therapy, and reconstructive type on complication rates. Premastectomy and postmastectomy questionnaires were used to assess patient satisfaction and were also analyzed using regression models. Of the 128 patients (199 breasts) who were randomized in the trial, 108 patients (167 breasts) were available for analysis in stage III. There was no difference in the overall complication rates between the AlloDerm and DermaMatrix groups (6% versus 13.2%; P = 0.3) or the severity of those complications (P = 0.7). Obesity was a positive predictor for complications, regardless of reconstruction group (P = 0.02). Patient satisfaction was positive overall and did not grossly vary between AlloDerm and DermaMatrix groups. Findings from the BREASTrial conclude that AlloDerm and DermaMatrix exhibit similar histologic and clinical outcomes. Patient satisfaction is also similar between matrices. Obesity is a predictor of complications, and acellular dermal matrices should be used with caution in these patients.

Broyles et al (2021) conducted a Level 1 prospective, randomized, controlled, multicenter clinical trial to assess complications associated with the use of two human acellular dermal matrices in immediate postmastectomy implant-based breast reconstruction across seven clinical sites. Group A patients received FlexHD Pliable (113 patients with 187 breast reconstructions), and group B patients received AlloDerm RTU (117 patients with 197 breast reconstructions). There was no significant difference with respect to patient demographics, indications, comorbidities, and reconstruction approach between groups. Mean follow-up time was 10.7 ± 3.2 months. There was no statistical difference in the overall matrix-related complications between groups A and B (4.3 percent versus 7.1 percent, p = 0.233). Obesity (OR, 1.14; 95 percent CI, 1.05 to 1.24; p = 0.001) and prepectoral placement of

matrix (OR, 4.53; 95 percent CI, 1.82 to 11.3; p = 0.001) were independently associated with greater risks of overall matrix-related complications. The authors concluded that the results support the use of human acellular dermal matrices in implant-based breast reconstruction and demonstrates no significant difference in matrix-related complication rates between FlexHD Pliable and AlloDerm RTU.

Berger et al (2024) published a multicenter retrospective comparative study of patients undergoing immediate prosthesis-based breast reconstruction (iPBR) with SurgiMend PRS, AlloDerm, or DermACELL between January 2014 to July 2022. Primary outcomes included rates of unplanned explantation and total reconstructive failure. Secondary outcomes included 90-day postoperative complications and long-term rates of capsular contracture development. A total of 738 patients (1228 breasts) underwent iPBR during the study period; 405 patients received DermACELL (54.9%), 231 received AlloDerm (31.3%), and 102 received SurgiMend PRS (13.8%). Rates of short-term complications, total reconstruction failure, reoperation within 90 days, capsular contracture, and unplanned explantation were comparable. These findings remained true upon multivariate analysis accounting for baseline differences between cohorts, whereby ADM type was not an independent predictor of any outcome of interest. Conversely, factors such as body mass index, diabetes mellitus, smoking history, neoadjuvant and adjuvant chemotherapy, adjuvant radiation, skin-sparing mastectomy, Wise pattern and peri-areolar incisions, use of tissue expanders, and a subpectoral plane of insertion were significant predictors of postoperative complications. The authors concluded that low rates of complications support the equivalency of fetal bovine and human-derived ADMs in iPBR. Patient characteristics and operative approach are likely more predictive of postoperative outcomes than ADM derivative alone.

Asaad et al (2023) performed a retrospective review of consecutive patients who underwent immediate prepectoral IBR from January of 2018 through December of 2019. Surgical outcomes and PROs (using the BREAST-Q) were compared among the AlloDerm, SurgiMend, and Dermacell ADMs. Overall, 557 breasts (383 patients) were included (78.6% AlloDerm, 14% SurgiMend, 7.4%Dermacell). Patients in the Dermacell group were older (P = 0.001) and more likely to have diabetes (P = 0.001) compared with AlloDerm and SurgiMend patients. Other patient characteristics were similar among the three groups. The overall complication rate was equivalent among the three ADM groups (AlloDerm 27% vs SurgiMend 33% vs Dermacell 39%; P = 0.209). Multivariable frailty models demonstrated that the type of ADM was not significantly associated with overall complications, infection, major complications, or device explantation. BREAST-Q satisfaction with breasts, psychosocial well-being, and sexual well-being were also similar among the three ADM groups (P =0.109, P = 0.439, P = 0.152, respectively). The authors concluded this study shows three (3) of the most commonly used ADMs in the United States have similar surgical outcomes and PROs when used for prepectoral IBR. No significant differences in infection, overall complications, or device removal rates were identified among AlloDerm, SurgiMend, and Dermacell.

A retrospective review compared complication rates following breast reconstruction with AlloDerm or FlexHD in 382 consecutive women (547 breasts) (Liu 2014). A total of 81% of the patients underwent immediate reconstruction; 165 used AlloDerm, and 97 used FlexHD. Mean follow-up was 6.4 months. Compared with breast reconstruction without use of AlloDerm or FlexHD, ADM had a

higher rate of delayed healing (20.2% versus 10.3%), although this finding might be related to differences in fill volumes. In univariate analysis, there were no significant differences in complications (return to the operating room, surgical site infection, seroma, hematoma, delayed healing, or implant loss) between AlloDerm and FlexHD. In multivariate analysis, there were no significant differences between AlloDerm and FlexHD for the return to the operating room, surgical site infection, seroma, or delayed healing. Independent risk factors for implant loss included the use of FlexHD, single-stage reconstruction, and smoking.

Another retrospective review compared complication rates following use of AlloDerm (n=136) or FlexHD (n=233) in a consecutive series of 255 patients (369 breasts) (Seth 2013). Total complication rates for the two products were similar (19.1% for AlloDerm and 19.3% for FlexHD). Analysis by type of complication showed no significant difference between the products, and regression analysis controlling for differences in baseline measures found that the type of ADM was not a risk factor for any complication.

A retrospective review of complication rates when AlloDerm (n=49), DermaMatrix (n=110), or FlexHD (n=62) was used for tissue expander breast reconstruction (Brooke 2012). Clinically significant complications were defined as cellulitis, abscess, seroma, expander leak or puncture, skin necrosis, wound dehiscence, or hematoma. The total clinically significant complication rate was 22% with AlloDerm, 15% with DermaMatrix, and 16% with FlexHD (not significantly different). Infectious complication rates for the three products were the same at 10%. When compared with breast reconstruction without an ADM (n=64), there was no significant difference in the total complication rate (17% vs 11%), but there was a trend toward a higher incidence of infectious complications (10% vs 2%, p=0.09).

Nasal Repairs, Hernia Repair, and Parotidectomy (Alloderm)

There is limited scientific evidence in the form of retrospective case series (Kissane 2012) to support the use of AlloDerm in rare cases of non-primary hernia repair when chronic infection contraindicates the use of mesh or other conventional repair.

Literature regarding the use of AlloDerm in parotidectomy also consists of small case series; however, the studies support that AlloDerm is beneficial in preventing Frey's syndrome after parotidectomy. A network meta-analysis sought to determine the best method for prevention of Frey syndrome after parotidectomy (Mashrah 2021). Thirty-four studies (n = 2987 patients) with five interventions, namely Alloderm (ADM), temporoparietal fascia (TPF), sternocleidomastoid muscle (SCM), superficial musculoaponeurotic system (SMAS), and free fat graft (FFG), were compared together and with no interposition barrier (NB). The results of NMA showed a statistically significant reduction in both subjective Frey syndrome (SFS) and objective Frey syndrome (OFS) when ADM, TPF, SMAS, FFG, and SCM were compared with NB. No statistical differences were observed when comparing ADM, SCM, SMAS, FFG, and TPF. TPF ranked the best of all treatments (59.4%) and was associated with the least incidence of SFS; whereas ADM ranked the best of all treatments (61.1%) and was associated with the least incidence of OFS.

A sponsored, retrospective study of real-world use of AlloDerm acellular dermal matrix in head and neck procedures in the U.S. was conducted for the period of October 2015 to March 2022

(Dominguez 2024). Descriptive statistics were used to describe surgery types and 30-day follow-up reoperations, graft complications, and all-cause healthcare resource utilization (HCRU). Among 431 patients (51.7% women), mean (SD) age was 52.2 (15.8) years. AlloDerm was most used with oral cavity reconstruction (35.3%), septal perforation repair/rhinoplasty (16.5%), and parotidectomy (13.0%). Most procedures were performed in outpatient settings (hospital, 90.0%; ambulatory surgical center, 8.6%). Over 30 days, less than 1% of patients (4 of 431) required reoperation with AlloDerm; 0.5% (2 of 431) had graft-related complications. Most (75.6%) patients had outpatient visits; few had an emergency room visit (7.9%) or inpatient claim (3.0%). The authors concluded real-world evidence indicates that AlloDerm is used in head- and neck-related procedures in US adults. Post-procedure complications and reoperations were uncommon during the follow-up period.

Burns (Integra Dermal Regeneration Matrix (Omnigraft), Biobrane, Epicel)

Carsin et al (2000) reported 5-year experience in a large, single center series of severely burned and otherwise traumatized patients given cultured epithelial autografts (CEA) (Epicel) from a single commercial laboratory. From 1991 to 1996, CEA were applied to a mean 37+/-17% of total body surface area (TBSA) of 30 patients. These patients had 78+/-10% average burn size, 65+/-16% average third-degree burn size, 90% prevalence of endoscopically confirmed inhalation injury and 37% prevalence of other serious conditions. CEA achieved permanent coverage of a mean 26+/-15% of TBSA, an area greater than that covered by conventional autografts (a mean 25+/-10% of TBSA). Survival was 90% of these severely burned and otherwise traumatized patients. Final CEA take was a mean 69+/-23%. In subset analyses, only younger age was significantly associated with better CEA take ($p = 0.0001$ in univariate analysis, $p<0.04$ in multivariate analysis, Student's t-test). Epicel CEA successfully provided extensive, permanent burn coverage in severely traumatized patients, proving an important adjunct to achievement of a high survival rate in a patient population whose prognosis previously had been poor. The authors concluded that CEA appeared to have a very high beneficial value in the management of burns >60% TBSA and in some cases it was very likely that CEA was a life-saving treatment.

Biobrane (Dow Hickman/Bertek Pharmaceuticals, Sugar Land, TX), a semi-permeable silicone device embedded with a nylon mesh and a porcine-derived collagen matrix, offers a promising alternative with advantages such as improved wound healing, reduced pain, and fewer dressing changes. A systematic review and meta-analysis (Jabarkhyl 2025) assessed the efficacy of Biobrane. Primary outcomes included burn wound healing time, hospital length of stay and infection rate, while secondary outcomes assessed the need for split-thickness skin grafts (STSGs), pain, and the number of dressing changes. Their data encompassed 781 burn wounds across 12 studies. The results showed that Biobrane significantly shortened wound healing time (mean difference, MD: 5.168 days, $p = 0.001$) and hospital length of stay (MD: 2.009 days, $p < 0.001$) compared to standard dressings. The infection rate was comparable (odds ratio, OR: 2.457, $p = 0.132$), and there was no difference in the requirement for STSGs (OR: 0.965, $p = 0.956$). This systematic review and meta-analysis demonstrate that Biobrane is an effective treatment for superficial pediatric burn injuries, offering faster wound healing, reduced pain and shorter hospital stays compared to traditional dressings.

A systematic review and meta-analysis were conducted to evaluate the role of various dermal

regeneration templates (DRTs) in comparison with split-thickness skin grafting in managing acute burn injuries after excision and debridement (Alkhonizy 2024). A total of 28 randomized clinical trials were assessed, encompassing a wide array of DRTs. The most frequently evaluated DRT, Integra Dermal Regeneration Template, not only showed potential for peripheral nerve reinnervation but also indicated a potential for a longer initial healing time, aligning with previous studies highlighting its efficacy in reducing scar formation and wound contracture. TransCyte displayed impressive rates of re-epithelialization and was found suitable for acute partial-thickness burns. Moreover, its low infection rate substantiates its antimicrobial properties and aligns with prior research.

The ReCell device has been evaluated in 2 manufacturer (AVITA Medical) sponsored RCTs (Holmes 2018, 2019). One RCT evaluated ReCell as an adjunct to meshed autologous skin grafting and the other compared ReCell head-to-head with skin grafting. Although the ReCell device was comparable to standard care on outcomes such as complete wound closure, confidence in the strength of the overall body of evidence is limited by individual study limitations and heterogeneity of populations, interventions, and outcome measures across studies. Additional RCT evidence regarding the intended use population is needed. The evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

Manning et al (2022) conducted a randomized, open-label trial with one of the investigators of the study being the developer of ReCell and the products were donated from their foundation. Forty-nine eligible foot wounds in 45 participants were randomized to receive an application of non-cultured autologous skin cells ("spray-on" skin; ReCell) or standard care interventions for large (>6 cm2), adequately vascularized wounds. A total of 32 (65.3%) index wounds were completely healed at 6 months, including 16 of 24 (66.7%) in the spray-on skin group and 16 of 25 (64.0%) in the standard care group (unadjusted OR [95% CI]: 1.13 (0.35-3.65), P = .845). Lower body mass index (P = .002) and non-plantar wounds (P = .009) were the only patient- or wound-related factors associated with complete healing at 6 months. The authors concluded that spray-on skin resulted in high rates of complete healing at 6 months in patients with large diabetes-related foot wounds but was not significantly better than standard care.

PROFESSIONAL GUIDELINE(S)

In February 2020, the Agency for Health Research and Quality (AHRQ) completed a technology assessment addressing Skin Substitutes for Treating Chronic Wounds. The assessment addresses 76 products commercially available in the U.S. that are used to manage or treat chronic wounds and are regulated by FDA. Based on FDA regulations, skin substitutes can be organized into four groups:

- human-derived products regulated as HCT/Ps (human cells, tissues, and tissue-based products)
- human- and human/animal-derived products regulated through PMA or humanitarian device exemption (HDE)
- animal-derived products regulated under the 510(k) process
- synthetic products regulated under the 510(k) process

Of those included in the tech assessment, 68 (89%) were categorized as acellular dermal substitutes,

mostly replacements from human placental membranes and animal tissue sources. Three systematic reviews and 22 RCTs examined use of 16 distinct skin substitutes, including acellular dermal substitutes, cellular dermal substitutes, and cellular epidermal and dermal substitutes in diabetic foot ulcers, pressure ulcers, and venous leg ulcers. Twenty-one ongoing clinical trials (all RCTs) examined an additional nine skin substitutes with similar classifications. Studies rarely reported clinical outcomes, such as amputation, wound recurrence at least two weeks after treatment ended, or patient related outcomes, such as return to function, pain, exudate, and odor. The large majority of skin substitute products listed in the report did not have efficacy data from RCTs. Industry funds most published studies and funded 20 of 22 RCTs included in this report, which raises significant concerns about possible publication bias or selective outcome reporting. The clearest implications of this Technical Brief are the lack of studies examining the effectiveness of most skin substitute products and the need for better designed and better reported studies providing more clinically relevant data.

The National Institute for Health and Care Excellence (NICE 2019) guidelines for diabetic foot problems: prevention and management recommend the following:

- Consider dermal or skin substitutes as an adjunct to standard care when treating diabetic foot ulcers, only when healing has not progressed and on the advice of the multidisciplinary foot care service.

NICE guidance on the ReCell system for treating skin loss, scarring, and depigmentation after burn injury (2020) recommended that there is insufficient evidence on its use in clinical practice, particularly in relation to which patients might benefit most from its use, to support the case for its routine adoption in the NHS.

The Association of Breast Surgery and the British Association of Plastic, Reconstructive and Aesthetic Surgeons published joint practice guidelines (Whisker 2021) regarding biological and synthetic mesh assisted breast reconstruction procedures. They make the following recommendations:

- Biological or synthetic mesh may be used in the following settings:
    - Implant-based total breast reconstruction after mastectomy; both for breast cancer patients and in women undergoing risk-reducing surgery
        - Immediate reconstruction
        - Total pre-pectoral or partially sub-pectoral reconstruction
    - Revision of cosmetic concerns following breast surgery
        - In the clinical setting of revising implant-based reconstructions e.g., correction of "bottoming out," symmastia and implant rippling
        - Revision of cosmetic concerns following oncoplastic breast conserving surgery e.g., correction of "bottoming out" after mammoplasty or mastopexy
    - Congenital asymmetry/deformity surgery

- There are a large number of products available, and the product range is rapidly evolving. There is no clear consensus on the ideal biological or synthetic mesh or evidence to inform mesh selection. The guideline group recommends consideration of the following when selecting a product:
    - Biological versus synthetic
        - Biological products (e.g., ADMs) are usually animal derived. Ensure the patient is informed and comfortable with the mesh origin.
        - Synthetic mesh may be composed from absorbable and/or non-absorbable materials.

The International Society for Burn Injury (ISBI) published practice guidelines for burn care (2016) which make the following recommendations:

- Modern dressings and biologic membranes are the preferred dressing choices as they ensure the best means against infection as well as scar quality outcome.
- Raw area, similar to the superficial partial thickness burn and graft donor site, is an area of the body that lacks epithelial covering. Raw areas should be dressed with a closed technique. Biologic dressings seem to be superior to nonbiologic dressings. Type (temporary or semi-permanent) and frequency of dressing are decided according to the wound condition and availability of these products.
- Amniotic membrane—whether it was used as fresh, lyophilized, and/or irradiated—showed superiority in most of the studies compared to conventional dressing, particularly in chronic burn wounds. Amniotic membrane was very effective, even with resistant strains like Pseudomonas, in areas with scarce blood supply, such as the cornea.
- After excision or debridement of the deep burn wound, it is essential that the wound is covered with autograft skin or an appropriate skin substitute. A wound too large to be safely repaired with autograft should be repaired with allograft or skin substitute. Failure to achieve adequate wound coverage after excision commonly results in invasive infection, or at best, desiccation of the exposed wound surface.
- Five substitute alternatives can be used to replace autograft following excision or debridement of deep burn wounds. These alternatives are described below.
    - Human allograft skin
        - Cryopreserved allograft is widely used and can provide good quality temporary skin cover for excised wounds for several weeks, until rejection occurs. Cryopreservation allows full donor-virus testing to be carried out so as to avoid risk of transmission of illness. Fresh allograft is the most effective skin replacement, and takes for many weeks, but fresh cadaveric allograft is seldom readily available. Fresh donor-related allograft (typically from a parent) may be suitable for small children but is not widely used. Glycerol-preserved or

lyophilized skin is nonviable, and functions as a very good biologic dressing rather than a vascularized graft. It can be very effective as a short-term cover (up to approximately 2 weeks) for excised wounds.

- Dermal regeneration matrices (or templates)
    - Following the successful introduction of a bovine collagen–based dermal regeneration template, a number of dermal regeneration products have been used. These biosynthetic products have been derived from bovine collagen, human allograft dermis, and porcine dermis, and also from synthetic substances. These acellular products are commonly based on collagen and produce a matrix on which a "neodermis" may regenerate. Broadly, these acellular products can be divided into those for either two- or one-stage use. The two-stage products are most suitable for acute major burns, as they provide temporary wound closure, prior to secondary autografting later with thin autograft or cultured cells (for instance: with Integra short-term wound closure is achieved with a surface silicone layer, which is removed prior to autografting at approximately 3 weeks, when ideally the patient is more stable). The one-stage use products offer the advantage of enhanced dermal reconstruction with very thin autograft harvest, but if used immediately after burn injury, they require a donor site of the full extent of the wound. Of techniques evolved to date for major burn injuries, the dermal regeneration matrices are probably the closest to producing a widely available, reliable "synthetic skin. However, they do require full coverage with autograft epithelium. Disadvantages of the dermal regeneration matrices include a higher risk of problems with infection than with autograft or allograft, and relatively high cost which precludes anything but the most occasional use in an RLS.
- Xenograft-derived temporary wound coverage
    - The most common source of xenograft material for use in burns has been porcine-derived materials. These include untreated pigskin; cryopreserved pigskin; lyophilized porcine dermis; and popular biosynthetic products composed of porcine collagen with nylon and silicone. Considerable evidence supports the value of many of these materials when used as dressings in treatment of partial thickness wounds. For excised deep burn wounds, these xenograft products produce only short-term reliable wound cover (a few days). This can be useful in getting a patient safely through a major burn excision, before later application of definitive wound cover; but if used for more prolonged periods on excised wounds, the risks of invasive infection are higher.
- Amniotic membrane
    - Amniotic membrane is potentially universally available as good short-term coverage for excised wounds, and as a biologic dressing. In some RLS, its availability has been restricted by the cost of virus testing and by resultant

practical barriers to its use. Amniotic membrane can be stored as cryopreserved, irradiated, or glycerol-preserved and in many parts of the world this has proved a useful technique for short-term coverage of excised wounds.

- Cell-based therapies
    - Cultured epithelial cells have been widely used in burn treatment, both as autograft and allograft. Autograft takes time to grow, so it is not available as an immediate skin substitute for early major burn excision. Although cultured epithelium has gained acceptance for many indications in burn-wound management, problems with failure of adhesion of cultured epithelium to full thickness wound beds and poor durability of cover mean that cultured cells have not achieved a consistently effective role as the sole skin replacement for full thickness wounds. Cultured epithelium serves best where a native or regenerated dermis is present in the wound bed. Similarly, autologous epithelial cells in suspension, or stem cells of a variety of origins, have been shown to have significant potential for enhanced healing of a variety of burn wounds: partial thickness wounds, wounds covered with meshed skin grafts, or wounds where dermis (native or regenerated) is present. These techniques have huge potential for skin replacement therapies in future.

The Society for Vascular Surgery in collaboration with the American Podiatric Medical Association and the Society for Vascular Medicine published joint clinical practice guidelines for the management of the diabetic foot (Hingorani 2016). Their recommendations are as follows:

- "For DFUs that fail to demonstrate improvement (>50% wound area reduction) after a minimum of 4 weeks of standard wound therapy, we recommend adjunctive wound therapy options. These include negative pressure therapy, biologics (platelet-derived growth factor [PDGF], living cellular therapy, extracellular matrix products, amnionic membrane products), and hyperbaric oxygen therapy. Choice of adjuvant therapy is based on clinical findings, availability of therapy, and cost-effectiveness; there is no recommendation on ordering of therapy choice. Re-evaluation of vascular status, infection control, and off-loading is recommended to ensure optimization before initiation of adjunctive wound therapy (Grade 1B)."
- "Standard, comprehensive care should include wound off-loading, local wound debridement, control of edema, control of bioburden, and wound moisture balance with appropriate dressings. Standard of care for diabetic foot ulcerations will lead to improvement in the majority of cases, and only in those cases without improvement should adjunctive modalities be used."
- "We suggest consideration of living cellular therapy using a bilayered keratinocyte/fibroblast construct or a fibroblast-seeded matrix for treatment of DFUs when recalcitrant to standard therapy (Grade 2B)."
- "Apligraf (Organogenesis, Canton, Mass) is a cultured bilayer skin substitute originating from neonatal foreskin. A bovine collagen lattice is used as a base to support the organization of dermal fibroblasts and epithelial cells seeded after expansion of the separated neonatal cells. A

layer of allogeneic keratinocytes is cultured over the fibroblast layer to form a stratified epidermis. The bilayer has a structure similar to human skin, with the absence of hair follicles or sweat glands. The growth factors and cytokines secreted by the cellular components of Apligraf include fibroblast growth factor, VEGF, PDGF, transforming growth factor b, and multiple interleukins, paralleling those secreted by healthy human skin. The product requires a well-granulated wound bed in which exudate and bacterial levels have been controlled to yield positive results."

- "Dermagraft (Organogenesis) is an allogeneic dermal fibroblast culture derived from human neonatal foreskin samples and grown on a biodegradable scaffold. The resulting three-dimensional matrix can be implanted into chronic nonhealing wounds to supply functional fibroblasts and their corresponding expressed proteins. The scaffold biodegrades during a 1- to 2-week period, leaving behind only cellular components and proteins. Several in vitro studies have evaluated the ability of Dermagraft to express clinically significant quantities of growth factors after cryopreservation and thawing. VEGF, PDGF-A, and insulin-like growth factor I were all found to recover to significant levels as measured by enzyme-linked immunosorbent assay in wounds to which Dermagraft was applied."
- "We suggest consideration of the use of extracellular matrix products employing acellular human dermis or porcine small intestinal submucosal tissue as an adjunctive therapy for DFUs when recalcitrant to standard therapy (Grade 2C)."
- "A variety of tissue constructs have recently become available, approved through the 510K mechanism as adjunctive therapies for the healing of chronic wounds including DFUs. This includes products incorporating human tissue (acellular dermis, amniotic membrane, cryopreserved skin, others) or animal tissue (bladder tissue, pericardial tissue, intestinal submucosa). Of the multitude of these products, only two have been found to provide benefit compared with standard DFU treatment. A porcine small intestinal submucosa (SIS) construct (OASIS; Cook Biotech, West Lafayette, Ind) has been tested in a prospective randomized trial."
- "An acellular human dermal matrix (Graftjacket; Wright Medical Technology, Memphis, Tenn) was studied in a prospective randomized multicenter trial in 87 patients with DFUs compared with standard care. Significantly more wounds treated with the human dermal matrix healed at 12 weeks (69.6%) than with control."
- "We recommend that patients with DFU have pedal perfusion assessed by ABI, ankle and pedal Doppler arterial waveforms, and either toe systolic pressure or transcutaneous oxygen pressure (TcPO2) annually (Grade 1B)."

REGULATORY STATUS

The U.S. Food and Drug Administration (FDA) does not refer to any single product or class of products as "skin substitutes". Products in this review cover products that do not require FDA approval or clearance as well as a number of products cleared through the 510(k) pathway with a variety of FDA product codes. A large number of artificial skin and soft-tissue products are commercially available or in development. Commercial availability is not a reflection of a product's

regulatory status.

Human Amniotic Membrane and Acellular Dermal Matrix Products

Allograft ADM products derived from donated cadaveric human skin tissue are supplied by tissue banks compliant with standards of the American Association of Tissue Banks and FDA guidelines. The processing removes the cellular components (i.e., epidermis, all viable dermal cells) that can lead to rejection and infection. ADM products from human skin tissue are regarded as minimally processed and not significantly changed in structure from the natural material; FDA classifies ADM products as banked human tissue and, therefore, not requiring FDA approval for homologous use.

Human amniotic membrane is classified by the FDA as banked human tissue and, therefore, does not require FDA approval.

AlloDerm (LifeCell Corp.) is an ADM (allograft) tissue-replacement product created from native human skin and processed so that the basement membrane and cellular matrix remain intact. Originally, AlloDerm required refrigeration and rehydration before use. It is currently available in a ready-to-use product stored at room temperature. An injectable micronized form of AlloDerm (Cymetra) is available. AlloDerm is classified by the FDA as human tissue and is approved for use in burns and full-thickness wounds.

AlloPatch (Musculoskeletal Transplant Foundation) is an acellular human dermis allograft derived from the reticular layer of the dermis and marketed for wound care. This product is also marketed as FlexHD for post mastectomy breast reconstruction.

Cortiva (previously marketed as AlloMax Surgical Graft and before that NeoForm) is an acellular non-cross-linked human dermis allograft.

DermACELL (LifeNet Health) is an allogeneic ADM processed with proprietary technologies MATRACELL and PRESERVON.

DermaMatrix (Synthes) is a freeze-dried ADM derived from donated human skin tissue. DermaMatrix Acellular Dermis is processed by the Musculoskeletal Transplant Foundation.

Epicord Dehydrated Human Umbilical Cord (DHUC) Allograft (MIMEDX Group, Inc.) is a placental-based tissue product that acts as a barrier and provides a protective environment to help support the healing process. It is comprised of an extracellular matrix of hyaluronic acid (HA) and collagen. Epicord is regulated as a human cell, tissue, or cellular or tissue-based product.

EpiFix (MIMEDX Group, Inc.) is a placental tissue allograft composed of dehydrated human amnion/chorion membrane (DHACM). EpiFix is regulated as a human cell, tissue, or cellular or tissue-based product.

FlexHD and the newer formulation FlexHD® Pliable (Musculoskeletal Transplant Foundation) are acellular hydrated reticular dermis allograft derived from donated human skin.

GRAFIX (Smith and Nephew) lyopreserved and cryopreserved placental membrane products and surgical applications retain all components of placental tissue, including native placental cells.

GraftJacket Regenerative Tissue Matrix (also called GraftJacket Skin Substitute; KCI) is an acellular

regenerative tissue matrix that has been processed from human skin supplied from U.S. tissue banks. The allograft is minimally processed to remove the epidermal and dermal cells while preserving dermal structure. GraftJacket Xpress is an injectable product.

TheraSkin (LifeNet Health) is a cryopreserved split-thickness human skin allograft composed of living fibroblasts and keratinocytes and an extracellular matrix in epidermal and dermal layers. TheraSkin® is derived from human skin allograft supplied by tissue banks compliant with the American Association of Tissue Banks and FDA guidelines. It is considered a minimally processed human cell, tissue, and cellular- and tissue-based product by the FDA.

Although frequently used by surgeons for breast reconstruction, FDA does not consider this homologous use and has not cleared or approved any surgical mesh device (synthetic, animal collagen-derived, or human collagen-derived) for use in breast surgery. The indication of surgical mesh for general use in "Plastic and reconstructive surgery" was cleared by the FDA before surgical mesh was described for breast reconstruction in 2005. FDA states that the specific use of surgical mesh in breast procedures represents a new intended use and that a substantial equivalence evaluation via 510(k) review is not appropriate and a pre-market approval evaluation is required.

The FDA issued a statement on March 31, 2021, stating while used for other types of reconstruction, the FDA has not cleared or approved ADM for use in breast reconstruction. The statement informed patients, caregivers, and health care providers that certain ADM products used in implant-based breast reconstruction may have a higher chance for complications or problems. The FDA requests prompt reporting of adverse events to help evaluate the risks.

FDA product codes: FTM, OXF.

<u>Xenogeneic Products</u>

Oasis Wound Matrix (Cook Biotech) is a collagen scaffold (extracellular matrix) derived from porcine small intestinal submucosa. In 2000, it was cleared for marketing by the FDA through the 510(k) process for the management of partial- and full-thickness wounds, including pressure ulcers, venous ulcers, diabetic ulcers, chronic vascular ulcers, tunneled undermined wounds, surgical wounds, trauma wounds, and draining wounds.

PriMatrix (TEI Biosciences; a subsidiary of Integra Life Sciences) is a xenogeneic ADM processed from fetal bovine dermis. It was cleared for marketing by the FDA through the 510(k) process for partial- and full-thickness wounds; diabetic, pressure, and venous stasis ulcers; surgical wounds; and tunneling, draining, and traumatic wounds.

The FDA issued a class II recall for PriMatrix on September 30, 2024, for possible out of specification endotoxin test results due to issues with in-process and finished goods endotoxin testing.

SurgiMend PRS (TEI Biosciences, a subsidiary of Integra Life Sciences) is a xenogeneic ADM processed from fetal and neonatal bovine dermis.

FDA Product codes: KGN, FTL, FTM.

<u>Living Cell Therapy</u>

Apligraf (Organogenesis) is a bilayered living cell therapy composed of an epidermal layer of living human keratinocytes and a dermal layer of living human fibroblasts. Apligraf is supplied as needed, in 1 size, with a shelf-life of 10 days. In 1998, it was approved by the FDA for use in conjunction with compression therapy for the treatment of noninfected, partial- and full-thickness skin ulcers due to venous insufficiency and in 2001 for full-thickness neuropathic diabetic lower-extremity ulcers nonresponsive to standard wound therapy.

Dermagraft (Organogenesis) is composed of cryopreserved human-derived fibroblasts and collagen derived from newborn human foreskin and cultured on a bioabsorbable polyglactin mesh scaffold. Dermagraft has been approved by the FDA for repair of diabetic foot ulcers.

Epicel (Genzyme Biosurgery) is an epithelial autograft composed of a patient's own keratinocytes cultured ex vivo and is FDA-approved under a humanitarian device exemption for the treatment of deep dermal or full-thickness burns comprising a total body surface area of 30% or more. It may be used in conjunction with split-thickness autografts or alone in patients for whom split-thickness autografts may not be an option due to the severity and extent of their burns.

FDA product codes: FTM, PFC, OCE, ODS.

Autologous Cell Harvesting Device

Recell (Avita Medical) was initially approved by the FDA in September 2018 under the premarket approval (PMA) process (PMA BP170122). It is an autologous cell harvesting device indicated for the treatment of acute partial-thickness thermal burn wound when used by an appropriately licensed healthcare professional at the patient's point of care to prepare autologous RES Regenerative Epidermal Suspension. The initial indication was for use in patients 18 years of age and older in combination with meshed autografting. Subsequently, indications were expanded to include direct application to acute partial-thickness thermal burn wounds in patients 18 years of age and older or application in combination with meshed autografting for acute full-thickness thermal burn wounds in pediatric as well as adult patients and for and full-thickness skin defects after traumatic avulsion (e.g., degloving) or surgical excision (e.g., necrotizing tissue infection) or resection (e.g., skin cancer) in patients 15 years of age and older.

FDA product code: QCZ.

Biosynthetic Products

Biobrane/Biobrane-L (Smith and Nephew) is a biosynthetic wound dressing constructed of a silicon film with a nylon fabric partially embedded into the film. The fabric creates a complex 3-dimensional structure of trifilament thread, which chemically binds collagen. Blood/sera clot in the nylon matrix, adhering the dressing to the wound until epithelialization occurs. Biobrane was granted pre-market approval by the FDA as a temporary covering of full thickness burns until autografting is clinically appropriate.

Integra Dermal Regeneration Template (also marketed as Omnigraft Dermal Regeneration Matrix; Integra Life Sciences) is a bovine, collagen/glycosaminoglycan dermal replacement covered by a silicone temporary epidermal substitute. It was approved by the FDA for use in the post excisional

treatment of life-threatening full-thickness or deep partial-thickness thermal injury where sufficient autograft is not available at the time of excision or not desirable because of the physiologic condition of the patient, for the repair of scar contractures when other therapies have failed.

In January 2016, the FDA approved the Integra Dermal Regeneration Template, marketed as Omnigraft, for use in the treatment of partial- and full-thickness neuropathic diabetic foot ulcers that are greater than six weeks in duration, with no capsule, tendon, or bone exposed, when used in conjunction with standard diabetic ulcer care.

TransCyte (Advanced Tissue Sciences) consists of human dermal fibroblasts grown on nylon mesh, combined with a synthetic epidermal layer, and was approved by the FDA in 1997. TransCyte is intended as a temporary covering over burns until autografting is possible. It can also be used as a temporary covering for some burn wounds that heal without autografting.

FDA product codes: FRO, MDD, MGR.

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
15011 (E/I)	Harvest of skin for skin cell suspension autograft; first 25 sq cm or less
15012 (E/I)	Harvest of skin for skin cell suspension autograft; each additional 25 sq cm or part thereof (List separately in addition to code for primary procedure)
15013 (E/I)	Preparation of skin cell suspension autograft, requiring enzymatic processing, manual mechanical disaggregation of skin cells, and filtration; first 25 sq cm or less of harvested skin
15014 (E/I)	Preparation of skin cell suspension autograft, requiring enzymatic processing, manual mechanical disaggregation of skin cells, and filtration; each additional 25 sq cm of harvested skin or part thereof (List separately in addition to code for primary procedure)
15015 (E/I)	Application of skin cell suspension autograft to wound and donor sites, including application of primary dressing, trunk, arms, legs; first 480 sq cm or less
15016 (E/I)	Application of skin cell suspension autograft to wound and donor sites, including application of primary dressing, trunk, arms, legs; each additional 480 sq cm or part thereof (List separately in addition to code for primary procedure)
15017 (E/I)	Application of skin cell suspension autograft to wound and donor sites, including application of primary dressing, face, scalp, eyelids, mouth, neck, ears, orbits, genitalia, hands, feet, and/or multiple digits; first 480 sq cm or less

Code	Description
15018 (E/I)	Application of skin cell suspension autograft to wound and donor sites, including application of primary dressing, face, scalp, eyelids, mouth, neck, ears, orbits, genitalia, hands, feet, and/or multiple digits; each additional 480 sq cm or part thereof (List separately in addition to code for primary procedure)
15271	Application of skin substitute graft to trunk, arms, legs, total wound surface area up to 100 sq cm; first 25 sq cm or less wound surface area
15272	each additional 25 sq cm wound surface area, or part thereof
15273	Application of skin substitute graft to trunk, arms, legs, total wound surface area greater than or equal to 100 sq cm; first 100 sq cm wound surface area, or 1% of body area of infants and children
15274	each additional 100 sq cm wound surface area, or part thereof, or each additional 1% body area of infants and children, or part thereof
15275	Application of skin substitute graft to face, scalp, eyelids, mouth, neck, ears, orbits, genitalia, hands, feet, and/or multiple digits, total wound surface area up to 100 sq cm; first 25 sq cm or less wound surface area
15276	each additional 25 sq cm wound surface area, or part thereof
15277	Application of skin substitute graft to face, scalp, eyelids, mouth, neck, ears, orbits, genitalia, hands, feet, and/or multiple digits, total wound surface area greater than or equal to 100 sq cm; first 100 sq cm wound surface area, or 1% of body area of infants and children
15278	each additional 100 sq cm wound surface area, or part thereof, or each additional 1% body area of infants and children, or part thereof
15777	Implantation of biologic implant (e.g., acellular dermal matrix) for soft tissue reinforcement (i.e., breast, trunk)
15778	Implantation of absorbable mesh or other prosthesis for delayed closure of defect(s) (i.e., external genitalia, perineum, abdominal wall) due to soft tissue infection or trauma

ICD10 Codes

Code	Description
C07	Malignant neoplasm of parotid gland
C50.011-C50.019	Malignant neoplasm of nipple and areola, female breast (code range)
C50.111-C50.119	Malignant neoplasm of central portion of female breast (code range)
C50.211-C50.219	Malignant neoplasm of upper-inner quadrant of female breast (code range)
C50.221-C50.229	Malignant neoplasm of upper-inner quadrant of male breast (code range)
C50.311-C50.319	Malignant neoplasm of lower-inner quadrant of female breast (code range)
C50.321-C50.329	Malignant neoplasm of lower-inner quadrant of male breast (code range)
C50.411-C50.419	Malignant neoplasm of upper-outer quadrant of female breast (code range)
C50.421-C50.429	Malignant neoplasm of upper-outer quadrant of male breast (code range)
C50.511-C50.519	Malignant neoplasm of lower-outer quadrant of female breast (code range)

Code	Description
C50.521-C50.529	Malignant neoplasm of lower-outer quadrant of male breast (code range)
C50.611-C50.619	Malignant neoplasm of axillary tail of female breast (code range)
C50.621-C50.629	Malignant neoplasm of axillary tail of male breast (code range)
C50.811-C50.819	Malignant neoplasm of overlapping sites of female breast (code range)
C50.821-C50.829	Malignant neoplasm of overlapping sites of male breast (code range)
C50.911-C50.919	Malignant neoplasm of unspecified site of female breast (code range)
C50.921-C50.929	Malignant neoplasm of unspecified site of male breast (code range)
D05.00-D05.92	Carcinoma in situ of breast (code range)
D11.0-D11.9	Benign neoplasm of major salivary gland (code range)
D37.030-D37.039	Neoplasm of uncertain behavior of the salivary glands (code range)
E08.621	Diabetes mellitus due to underlying condition with foot ulcer
E09.621	Drug or chemical induced diabetes mellitus with foot ulcer
E10.621	Type 1 diabetes mellitus with foot ulcer
E11.621	Type 2 diabetes mellitus with foot ulcer
E13.621	Other specified diabetes mellitus with foot ulcer
I83.001-I83.009	Varicose veins of unspecified lower extremity with ulcer (code range)
I83.011-I83.029	Varicose veins of lower extremity with ulcer (code range)
I83.201-I83.229	Varicose veins of lower extremity with both ulcer and inflammation (code range)
I87.311-I87.319	Chronic venous hypertension (idiopathic) with ulcer (code range)
K11.1-K11.9	Disease of salivary gland (code range)
K43.0-K43.2	Incisional hernia (code range)
L97.101-L97.929	Non-pressure chronic ulcer of lower limb, not elsewhere classified (code range)
T20.00XA-T25.399S	Burns - by site and degree of burn (code range)
T30.0	Burn of unspecified body region, unspecified degree
T30.4	Corrosion of unspecified body region, unspecified degree

Code	Description
T31.0-T31.99	Burns (code range)
T32.0-T32.99	Corrosions (code range)
Z85.3	Personal history of malignant neoplasm of breast
Z90.10-Z90.13	Acquired absence of breast and nipple (code range)

Skin substitutes are not addressed in National or Regional Medicare coverage determinations or policies.

PRODUCT DISCLAIMER

- Services are contract dependent; if a product does not cover a service, medical policy criteria do not apply.
- If a commercial product (including an Essential Plan or Child Health Plus product) covers a specific service, medical policy criteria apply to the benefit.
- If a Medicaid product covers a specific service, and there are no New York State Medicaid guidelines (eMedNY) criteria, medical policy criteria apply to the benefit.
- If a Medicare product covers a specific service, and there is no national or local Medicare coverage decision for the service, medical policy criteria apply to the benefit.

POLICY HISTORY/REVISION	
Committee Approval Dates	
New:05/16 **Revised**:01/17, 05/17, 01/18, 03/18, 01/19, 11/19, 09/20, 11/20, 9/21, 11/21, 3/22, 7/22, 11/22, 1/23, 5/23, 7/23, 11/23, 1/24, 5/24, 7/24, 9/24, 3/25, 5/25, 7/25, 11/25 **Reviewed**:05/18, 05/19, 05/20, 5/21, 9/26	
Date	**Summary of Changes**
08/20/26	• Annual review, policy intent unchanged, code edit, added CPT codes 15011-15018.
1/1/2026	• Transitioned Skin Substitutes for Wound Healing & Surgical Intervention policy, 1370/20.000486 to Lifetime Healthcare Companies policy template.
09/30/25	• Off-cycle policy update, code edit, added HCPCS codes A2036-A2039 and Q4383-Q4397. Policy intent unchanged.
7/1/2025	• Clarified verbiage under General Requirements. • Added new codes Q4368 – Q4382 to Exclusions section. • Added statement to Exclusions section regarding all other skin substitutes not otherwise mentioned in policy.
4/1/2025	• Added new skin substitute codes A2030-A2035 and Q4354-Q4367 to Exclusions section.
3/1/2025	• Added new codes to Exclusions section.
1/1/2025	• Added Amniofix to Exclusions section.
10/1/2024	• Removed AmnioBand from the Exclusions section and added coverage criteria.

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

7/1/2024	• Added new codes Q4311- Q4333 to Exclusions section.
4/1/2024	• Added new codes A2026, and Q4305-Q4310 to Exclusions section.
1/1/2024	• Added new codes Q4279, and Q4287-Q4304 to Exclusions section.
10/1/2023	• Added new codes A2022-A2025, and Q4285-Q4286 to Exclusions section.
7/1/2023	• Added new codes Q4272-Q4278 and Q4280-Q4284 to Exclusions section.
4/1/2023	• Removed deleted codes 49560-49566, 49568 and replaced with codes 49591-49596, 49600, 49605, 49606, 49610-49618. • **Added new codes A2019-A2021 and Q4265-Q4271 to exclusions section.**
2/1/2023	• Removed Flex HD (Q4128) from Exclusions and added coverage information under Position Statement. • **Added new codes effective 1/1/23 to Exclusions: Q4262, Q4263, and Q4264.**
10/1/2022	• Added new codes A2014-A2018 to Exclusions section.
7/1/22	• Added new codes Q4260 and Q4261 to Exclusions section.
4/1/22	• Updates made to Exclusions section to add new codes eff 1/1/22.
10/1/21* ***No change to effective date for this update**	• Updates made to Exclusions section to add new codes Q4251-Q4253 effective 10/1/21.
10/1/21	• Updated grid in Position Statement to align coverage with Medicare Advantage. • **Updated application limits for Apligraf, Primatrix, and Theraskin.**
3/1/21	• Updates made to Exclusions section.
1/1/21	• Removed termed code Q4172 from Exclusions. • **Revised code for Biovance.**
12/1/19	• Updates made to Exclusions section.

RESOURCE COORDINATION POLICY

CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: BIOFEEDBACK

POLICY EFFECTIVE DATE:	5/1/2024
Policy Control #:	1370/20.000067
Next Annual Review:	March 2027

DISCLAIMER

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgement when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

PROCEDURE CODES

90901, 90912, 90913, 90875, 90876, E0740

DESCRIPTION

Biofeedback is a therapeutic process that electronically monitors bodily functions, such as breathing, heart rate, blood pressure, skin temperature, and muscle tension, which are fed back to the individual by means of sounds, lights, or electronic gauges. It emphasizes relaxation and stress-reducing techniques. It is believed that by using these techniques, individuals can learn to control a variety of physiological responses formerly thought to be completely involuntary, and thereby help manage anxiety and pain commonly associated with stress reactions.

There are several different types of biofeedback. The biofeedback modality selected for therapy depends on the conditions to be treated. The most commonly used forms of biofeedback are (1) electromyography (EMG), which measures muscle tension; (2) thermal biofeedback, which measures skin temperature; and (3) neurofeedback or electroencephalography (EEG), which measures brain activity.

POSITION STATEMENT

CDPHP administers benefits for biofeedback therapy as indicated below.

Biofeedback Therapy

POLICY NAME: BIOFEEDBACK

CDPHP administers benefits for biofeedback therapy as a stand-alone procedure for the treatment of urinary stress and/or urge incontinence, or fecal incontinence and/or constipation.

Biofeedback Therapy and Electrostimulation

Biofeedback-assisted pelvic muscle exercise (PME) incorporates the use of an electronic or mechanical device to relay visual and/or auditory evidence of pelvic floor muscle tone, in order to improve awareness of pelvic floor musculature and to assist patients in the performance of PME.

CDPHP administers benefits for biofeedback therapy in conjunction with electrostimulation for the treatment of urinary incontinence or fecal incontinence and/or constipation, in cognitively intact patients who have failed a documented trial of PME* and have met all of the following criteria:

- Patient has had a complete genitourinary/gastrointestinal evaluation.
- Patient has tried and been unsuccessful at behavioral intervention to include appropriate muscle exercises or muscle reeducation, habit training, and diet modification.
- Patient must be cognitively intact and motivated to actively participate in a prescribed treatment plan, including practice and follow-through at home.

*A failed trial of PME is defined as no clinically significant improvement in urinary/fecal incontinence after completing four weeks of an ordered plan of pelvic muscle exercises.

Initial treatment for urinary/fecal incontinence utilizing biofeedback therapy in conjunction with electrostimulation is to be performed in a clinical setting (office or facility) under supervision.

- If documentation substantiates effectiveness of treatment, a non-implantable pelvic-floor electrical stimulation device will be approved for home use.

Non-Implantable Pelvic-Floor Electrical Stimulation (E0740)

Non-implantable pelvic-floor electrical stimulators provide neuromuscular electrical stimulation through the pelvic floor with the intent of strengthening and exercising pelvic-floor musculature. Stimulation is generally delivered by vaginal or anal probes connected to an external pulse generator.

CDPHP considers non-implantable pelvic-floor electrical stimulators to be durable medical equipment, and therefore subject to the terms and conditions of such as stated in the enrollee's contract.

The probes required for electrostimulation are considered to be a medical supply, and as such are not covered unless otherwise specified in the enrollee's contract.

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: BIOFEEDBACK

Biofeedback Therapy & Electromyography
E0740

Biofeedback therapy differs from electromyography, which is a diagnostic procedure used to record and study the electrical properties of skeletal muscle. An electromyography device may be used to provide feedback with certain types of biofeedback.

- No additional benefits are available for electromyography (51784, 51785) when performed in conjunction with biofeedback therapy.

POLICY CONSIDERATIONS

Benefits are provided for biofeedback services up to six sessions.

EXCLUSIONS

All conditions, other than those listed within this policy, are excluded from coverage to include, but not limited to, the following:

- Ordinary muscle tension states
- Migraine or muscle contraction (tension) headaches
- Vulvodynia

Biofeedback therapy performed in a setting other than in an office or other facility setting (e.g., home use of biofeedback therapy).

CDPHP PRODUCT VARIATIONS

CHILD HEALTH PLUS	Subject to all terms and conditions noted above in the policy.
MEDICARE ADVANTAGE	Subject to all terms and conditions noted above in the policy. Biofeedback therapy is covered under Medicare when it is reasonable and necessary for muscle reeducation of specific muscle groups or for treating pathological muscle abnormalities of spasticity, incapacitating muscle spasm, or weakness, and more conventional treatments (heat, cold, exercise, support) have not been successful. Coverage is allowed for medically necessary biofeedback training when performed by a physician or by a qualified non-physician.
SELECT PLAN/HARP	Biofeedback is not a covered service under the Select Plan/HARP benefit package.

POLICY HISTORY

This section is intended to provide only highlights of the policy changes. The policy should always be reviewed in its entirety to ensure a comprehensive understanding of coverage.

Effective Date	Update
5/1/2024	Relocated information on EEG Biofeedback/neurofeedback to the Non-Covered Technologies, 1370/20.000444 policy.
4/1/2022	Removed additional visits beyond the six-visit limitation will require documentation to support medical necessity.
7/1/2021	To clarify coverage, language updated to indicate coverage for urinary or fecal symptoms
1/1/2020	Removed deleted code 90911 and replaced with new codes 90912 and 90913 effective 1/1/2020.

This Resource Coordination Policy is the exclusive property of Capital District Physicians' Health Plan, Inc. (CDPHP®) and its affiliated companies, CDPHP Universal Benefits,® Inc. MEDICAL POLICY

Medical Policy Title	**Blepharoplasty and Brow Ptosis Repair**
Policy Number	**7.01.55**
Current Effective Date	**August 1, 2026**
Next Review Date	**March 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

Blepharoplasty

I. Upper eyelid blepharoplasty (reconstructive or functional) with or without functional levator muscle advancement, is considered **medically appropriate** for **ANY** of the following indications:

A. Ptosis when **ALL** the following are documented (See Policy Guidelines):

1. Upper eyelid margin is approaching less than or equal to 2.5 mm (1/4 of the diameter of the visible iris) of the corneal light reflex (marginal reflex distance or MRD);
2. Photographs in primary gaze (head and gaze straight ahead) demonstrating light reflex;
3. Functional limitations to the patient's vision; **and**
4. Visual field testing, with a written interpretation, demonstrates a minimum of 30 percent loss of upper field of vision with upper lid skin or upper margin in repose and an increase of 12 degrees or more with elevation (by the taping of the lid) to demonstrate potential correction by proposed procedure or procedures.

B. Dermatochalasis when **ALL** the following are documented (See Policy Guidelines):

1. Severe, redundant skin resting upon the eyelashes;
2. Photographs in primary gaze and/or lateral view showing eyelid tissue resting on or pushing down on the eyelashes;
3. Functional limitations to the patient's vision; **and**
4. Visual field testing, with a written interpretation, demonstrates a minimum of 30 percent loss of upper field of vision with upper lid skin or upper margin in repose and an increase of 12 degrees or more with elevation (by the taping of the lid) to demonstrate potential correction by proposed procedure or procedures.

C. Anophthalmia Socket when **ALL** the following are documented (See Policy Guidelines):

1. Improper fit of the eye prosthesis;

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

2. Difficulty wearing the prosthesis is caused by eyelid abnormality; **and**
3. Photographs showing the abnormality.

II. Lower eyelid blepharoplasty (reconstructive or functional) is considered **medically necessary** for **ALL** the following (See Policy Guidelines):

A. Diagnosis of **EITHER** of the following:

1. Vision is obstructed by the excess tissue; **or**
2. Eyes are dry and irritated; **and**

B. Clinical documentation includes **EITHER** of the following:

1. Functional limitation to the patient's vision; **or**
2. Eye irritation as shown in photographs and documentation of treatment.

III. Revisional blepharoplasty is considered **medically appropriate** when the criteria stated in Policy Statement I or II are met.

IV. If unilateral disease meets the above criteria, blepharoplasty of the opposite eyelid at the same time, may be considered **medically appropriate** as bilateral reconstructive blepharoplasty when **ALL** the following are met:

A. The opposite eyelid also exhibits abnormalities;

B. The opposite eyelid does not yet meet criteria for reconstructive blepharoplasty;

C. Clinical evidence indicates that the opposite eyelid will soon meet criteria for reconstructive blepharoplasty.

V. Cosmetic blepharoplasty is considered **not medically necessary** when performed to improve a patient's appearance, in the absence of any signs or symptoms of functional abnormalities.

Brow Ptosis Repair

VI. Brow ptosis repair (brow lift or browpexy) is considered **medically appropriate** when **ALL** the following are documented (See Policy Guidelines):

A. Brow ptosis causes functional visual impairment;

B. Photographs (lateral view preferred) showing the eyebrow below the supraorbital rim;

C. Visual field testing with a written interpretation.

RELATED POLICIES

Corporate Medical Policy

Cosmetic and Reconstructive Surgery, 1370/20.000071

POLICY GUIDELINE(S)

I. Peripheral visual field testing should be performed with the eyelid and brow in the resting

position to document a baseline superior visual field of 30 degrees or less from fixation and show an improvement of at least 12 degrees over baseline with eyelid and brow elevation. A superior visual field of 30 degrees or less that improves with eyelid and brow elevation corresponds to a functional superior visual field loss. If visual field testing is unable to be performed, a written explanation with photographs must accompany the request.

II. Documentation of the marginal reflex distance (MRD), which is the number of millimeters from the corneal light reflex or center of the pupil to the upper lid margin, is necessary for ptosis evaluation. For dermatochalasis MRD is not necessary but may be sufficient.

III. Photographic documentation of the patient while looking in primary gaze, upward-gaze, downward-gaze, and lateral views, which must be consistent with the degree of visual field impairment described in the medical records or demonstrated by the MRD measurements.

IV. Functional limitations may include:

A. Significant interference with vision or superior or lateral visual field (e.g., difficulty seeing objects approaching from periphery);

B. Difficulty reading due to superior visual field loss;

C. Looking through the eyelashes or seeing the upper eyelid skin; or

D. Significant congenital or acquired deformities or deformities beyond normal variations and accompanied by functional deficits. These must be evidenced by photographs. In some cases, visual fields may also be required.

DESCRIPTION

Blepharoplasty is eyelid surgery performed to remove fat, usually along with excess skin, from the upper and lower eyelids.

A functional blepharoplasty is performed when the range of vision is narrowed due to excessive redundant skin in the eyelid (dermatochalasis). During this procedure, various amounts of excess skin and sometimes fat are removed from the upper eyelid, thus increasing vision range. A blepharoplasty may be performed alone or in conjunction with other facial surgery procedures, such as a face lift or browlift, or to address cosmetic issues; however, it will not remove crow's feet or other wrinkles, eliminate dark circles under eyes, or lift sagging eyebrows.

Pseudoptosis is a condition in which the upper-lid skin becomes redundant and lax to such an extent that it "hoods" the eye, blocking peripheral vision on upward-gaze or the upper visual field when looking straight ahead. Dermatochalasis and/or muscle laxity is corrected with a reconstructive upper-lid blepharoplasty that removes excess tissue and restores visual function.

Eyelid ptosis, or blepharoptosis, is when the upper eyelid descends from its normal position or drops to approach or cover the pupil in one or both eyes. This condition can be caused by weakness of the levator muscle or tendon that lifts the eyelid. Treatment when vision is impaired is called a levator muscle advancement and involves tightening the levator muscle to lift the eyelid. In very severe cases involving weakened levator muscles, the eyelid is attached under the eyebrow. This allows the

forehead muscles to substitute for levator muscles in lifting the eyelid. A blepharoplasty may be performed along with levator muscle advancement when dermatochalasis is also present.

Cosmetic Blepharoplasty

When blepharoplasty is performed to improve a patient's appearance, in the absence of any signs and/or symptoms of functional abnormalities, the procedure is considered cosmetic.

Reconstructive Blepharoplasty

Reconstructive blepharoplasty is performed:

- to correct visual impairment caused by drooping of the eyelids (ptosis);
- to correct severe redundant skin (dermatochalasis) resting upon the eyelashes;
- to repair defects caused by trauma or tumor-ablative surgery;
- to treat periorbital sequelae of thyroid disease and nerve palsy;
- to relieve the painful symptoms of blepharospasm. This may involve rearrangement or excision of the structures within the eyelids and/or tissues of the cheek, forehead, and nasal areas.

Signs and symptoms commonly found in association with ptosis, pseudoptosis, blepharochalasis, and/or dermatochalasis include, but are not limited to, the following:

- visual field impairment in primary or downward gaze (e.g., reading position);
- lower than normal position of the eyelid relative to the pupil;
- excess skin that hangs over the edge of the eyelid;
- chronic dermatitis due to redundant skin;
- patients with anophthalmic socket experiencing prosthesis difficulties.

Primary essential (idiopathic) blepharospasm is a condition characterized by severe squinting, secondary to uncontrollable spasms of the periorbital muscles. Occasionally, it can be debilitating. Treatment includes extended blepharoplasty with wide resection of the orbicularis oculi muscle complex.

Cranial nerve palsy is the partial or complete palsy of the facial (seventh cranial) nerve or the oculomotor (third cranial) nerve and can cause true ptosis or pseudoptosis from marked periorbital muscle paralysis. Symptoms such as exposure keratitis and cornea erosion (facial nerve) or visual restriction (oculomotor nerve) may occur. When lesions involving the temporal branch of the facial nerve are present, treatment consists of reconstructive blepharoplasty, with or without browlift. Third-nerve palsy may require frontalis fascial suspension to obtain an adequate eyelid.

Thyroid disease symptoms may include unilateral or bilateral upper-eyelid retraction and proptosis (protruding eye). Frequently, medical therapy for the thyroid pathology will resolve these deformities, but occasionally, reconstructive blepharoplasty is necessary to prevent corneal exposure and erosion.

SUPPORTIVE LITERATURE

Ulas et al (2024) published results of a prospective study to evaluate the effect of upper eyelid

blepharoplasty surgery on corneal topography, visual field, ocular surface, meibography, corneal biomechanics and dry eye parameters. A total of 80 eyes of 40 patients were included. Following a detailed ophthalmological examination, standardized patient satisfaction questions were posed to patients before and after upper eyelid blepharoplasty surgery. Visual field test, non-invasive break up time (NIBUT), meibography, and corneal topography parameters were analyzed and evaluated. The mean (+) visible areas in the visual field were found to be 46.20±24.96 preoperatively, 56.73±21.98 at the 1st postoperative month and 65.96±18.5 at the 3rd month, which were statistically significant. NIBUT values preoperatively, at 1 month and at 3 months were 11.26±4.48, 11.16±4.5 and 10.14±4.0, respectively, which were statistically significant. Meibomian gland loss rates on meibography preoperatively and postoperatively at 1 and 3 months were found to be 30.24±8.3, 29.36±8.2 and 28.22±7.7 respectively and were statistically significant. With the scoring system after blepharoplasty, patients reported improvement in their symptoms. The authors concluded that upper eyelid blepharoplasty surgery is predicted to increase the quality of vision. It was observed that there was a functional and cosmetic improvement in the complaints of the patients after blepharoplasty. However, blepharoplasty may cause changes in eyelid dynamics and cause dry eye syndrome.

Hollander et al (2019) published results of a systematic review to assess the objective and subjective functional effects of upper blepharoplasty found in published literature. A total of 3525 studies were assessed, of which 28 studies were included. The intervention was defined as a solitary surgical upper blepharoplasty containing the removal of skin, with or without the removal of a strip of orbicularis oculi muscle and/or upper orbital fat. Eligible studies were randomized controlled trials, controlled trials, cohort studies, and case series ($n \geq 10$). Favorable outcomes after an upper blepharoplasty were reported and included enlarged visual field, enhanced quality of life related to fewer headaches and improved vision. Furthermore, sensitivity of the eyelids decreased, with differences in recovery. Outcomes for eyebrow height, astigmatism, contrast sensitivity, and eyelid kinematics were not consistent between the studies. No meta-analysis could be performed due to the limited scope of included studies and the great variety in outcomes and blepharoplasty techniques. The authors concluded, upper blepharoplasty is accompanied by a great variety of beneficial functional outcomes including an increased visual field and improvement in headache- and vision-related quality of life. Further research is needed, especially where results are conflicting (effects on eye dryness and eyebrow height) and/or the data are limited (contrast sensitivity, astigmatism).

PROFESSIONAL GUIDELINE(S)

The American Academy of Ophthalmology (AAO) published a report of Functional Indications for Upper Eyelid Ptosis and Blepharoplasty Surgery (Cahill 2011) that state blepharoplasty surgery was found to be functionally beneficial for the following quantitative findings: a MRD1 of ≤ 2 mm measured in primary gaze or a superior visual field loss of 12 degrees or 24%. They explain the unobstructed normal superior field measures approximately 50 degrees. Visual field impairment can occur when the MRD1 is less than 4 mm. With an MRD1 of 2 mm, the superior visual field impairment is in the range of 24–30%. This corresponds to 12-15 degrees of superior visual field loss. Preoperative indicators of improvement include margin reflex distance 1 (MRD1) of 2 mm or less, superior visual field loss of at least 12 degrees or 24%, down-gaze ptosis impairing reading and other

close-work activities, a chin-up backward head tilt due to visual axis obscuration, symptoms of discomfort or eye strain due to droopy lids, central visual interference due to upper eyelid position, and patient self-reported functional impairment.

AAO published a technology assessment regarding health-related quality of life (HRQL) outcomes for upper blepharoplasty and blepharoptosis surgery (Vagefi 2025). A meta-analysis of 20 studies utilizing validated instruments to assess HRQL and found blepharoptosis correction beneficial. The authors noted continued improvement at mean follow-up intervals ranging from 1.5 years to 3.6 years after surgery.

The American Society of Ophthalmic Plastic and Reconstructive Surgery (ASOPRS) published a white paper on functional blepharoplasty, blepharoptosis, and brow ptosis repair (2015). They recommend blepharoplasty when peripheral visual field testing performed with the eyelid and brow in the resting position documents a baseline superior visual field of 30 degrees or less from fixation and improvement of at least 12 degrees over baseline with eyelid and brow elevation. They further state unobstructed, the superior field normally measures approximately 45 to 50 degrees. An MRD of 2 mm corresponds to a superior visual field impairment of 12-15 degrees. Thus, a baseline superior visual field of 30-35 degrees corresponds to an MRD of 2mm. A superior visual field of 30 degrees or less that improves with eyelid and brow elevation corresponds to a functional superior visual field loss.

The American Society of Plastic Surgeons (ASPS) published a practice parameter for blepharoplasty in 2007. They state blepharoplasty is performed for both functional and aesthetic reasons. Functional issues include ptosis, floppy eyelid syndrome, blepharochalasis, dermatochalasis, herniated orbital fat, and visual field obstruction. Aesthetic reasons include a desire for a more youthful or less fatigued appearance. Preoperative consultation should evaluate the patient's reasons for seeking surgery. The physical examination should include an evaluation of the amount of skin on the upper and lower lids; distribution of orbital fat; vector of the lower eyelid; and physical characteristics of the skin including degree of elasticity and pigmentation. Ptosis of the upper eyelid is determined by measuring the palpebral fissure width and margin reflex distance. Levator excursion is also assessed. The forehead and eyebrow should be evaluated for brow ptosis. Preoperative photographs may be taken to meet the requirements of both the insurers and surgeons. Additional photographs may include upward and downward gaze as well as oblique views. Visual field assessment is required for functional blepharoplasty. Consultation with an optometrist or ophthalmologist may be arranged for field of vision examination. When there are visual field impairment blepharoplasty procedures are considered to be reconstructive. However, blepharoplasty procedures are most often performed to enhance appearance.

The American Society of Plastic Surgeons Evidence published evidenced based clinical practice guidelines regarding eyelid surgery for upper visual field improvement (Kim 2022). A group of experts from different disciplines was convened to develop guidelines for the management of upper visual field impairments related to eyelid ptosis and dermatochalasis. The goal was to provide evidence-based recommendations to improve patient care. A systematic literature review was performed including topics regarding documentation of the underlying cause for visual field impairment, selection of an appropriate surgical repair, assessment of the type of anesthesia, the use of

adjunctive brow procedures, and follow-up assessments. The review of the literature revealed varied complication rates and diverse treatment modalities for the correction of upper visual field deficit. Strong recommendations could not be made in most topic areas because of a paucity of methodologically sound studies in literature. More rigorously designed studies are needed to measure outcomes of interest, with fewer sources of potential error or bias. The workgroup recommends that for patients presenting with low upper eyelid position, clinicians obtain a clinical history, which should include an assessment of impact on visual field or activities of daily living; and perform a physical examination to assess upper eyelid position (ptosis) relative to the pupil (such as MRD-1) with photographic documentation and assessment of levator function (Level of evidence weak, moderate recommendation).

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgment when deciding the most appropriate care to enrollees. The CDPHP coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

Background

Anemia (defined as a hemoglobin [Hb] level <13 g/dL in men or <12 g/dL in women) is a common complication of chronic kidney disease (CKD). The anemia in CKD occurs as a normocytic anemia, meaning the red blood cells (RBCs) are a normal size but there is simply a low number of them. This occurs because the kidneys are responsible for producing a hormone called erythropoietin, which prompts the body to produce RBCs. Patients with CKD cannot make enough erythropoietin; therefore, low erythropoietin levels cause a low RBC count, leading to chronic anemia.

The risk for anemia increases with advancing stages of disease, with an estimated prevalence of 17% in Stage 3, 50% in Stage 4, and at least 54% in Stage 5 (end-stage renal disease [ESRD]). In individuals with CKD, severe anemia can increase the chance of developing cardiovascular (CV) problems because the heart gets less oxygen than normal and must work harder to pump enough RBCs to the organs and tissues. These patients are also at an increased risk for complications due to strokes. Cardiovascular disease is the leading cause of death in dialysis-dependent (DD) patients.

Epoetin alfa is a protein that stimulates the production of red blood cells by the same mechanism as endogenous erythropoietin. It is administered as an intravenous or subcutaneous injection and has multiple FDA approved indications. Epoetin alfa is available as both an innovator biologic reference product and as a biosimilar.

For a biological product to be labeled as a biosimilar, it must be shown that it is highly similar and has no differences from an existing FDA approved reference product (i.e., Epogen) by extensively analyzing the structure, purity, chemical identity, and bioactivity. It has been concluded that there are no clinically meaningful differences demonstrated through human pharmacokinetic/exposure and pharmacodynamic/responses, and assessment of immunogenicity. Biosimilars may be approved for all or a subset of the same indications as the reference product, depending on patent exclusivity. Biosimilars differ from generics in complexity, manufacturing processes, and in the data needed to demonstrate similarity for approval.

Summary

Effective Date of Policy:	2/12/26
Indications	Per product
Availability	Epogen, Procrit, Retacrit: available as single dose vials as 2,000 units (U)/mL, 3,000 U/mL, 4,000 U/mL, 10,000 U/mL, or 40,000 U/mL; available as multi-dose vials as 20,000 U/mL or 20,000 U/2 mL Aranesp: single dose vials as 25 mcg, 40 mcg, 60 mcg, 100 mcg, or 200 mcg; single dose prefilled syringes as 10 mcg/0.4 mL, 25 mcg/0.42 mL, 40 mcg/0.4 mL, 60 mcg/0.3 mL, 100 mcg/0.5 mL, 150 mcg/0.3 mL, 200 mcg/0.4 mL, 300 mcg/0.6 mL, or 500 mcg/1 mL Cosela: 300 mg single dose vial
Duration	Initial: 6 months Recertification: 6 months

Required Criteria for Approval

All of the following conditions for the requested indication must be met in order to approve therapy

Epoetin alfa		
Drug	**FDA Approved Indications**	**Preferred Product**
Epogen HCPCS: J0885 Procrit HCPCS: J0885 Retacrit HCPCS: Q5106	• Treatment of anemia due to zidovudine in patients with HIV infection • Treatment of anemia due to chronic kidney disease (CKD) in patients on dialysis and not on dialysis • Treatment of anemia due to concomitant myelosuppressive chemotherapy • Reduction of allogeneic red blood cell transfusions in patients undergoing elective, noncardiac, nonvascular surgery.	Retacrit and Procrit

A. Procrit and Retacrit are the preferred formulations of epoetin alfa and do not require prior authorization under the pharmacy or medical benefit.
B. Epogen does not require prior authorization under the medical or pharmacy benefit but may not be on all formularies.

Darbepoetin alfa	
Drug	**FDA Approved Indications**
Aranesp HCPCS: J0881	• Anemia Due to Chronic Kidney Disease • Anemia Due to Chemotherapy in Patients with Cancer

Aranesp does not require prior authorization under the medical or pharmacy benefit

Cosela (Trilaciclib)
 	
HCPCS Code: J1448
	• Must be ≥ 18 years of age AND
	• Must be prescribed by an oncologist or hematologist AND
	• Must have a diagnosis of extensive-stage small cell lung cancer (EC-SCLC) AND
	• Must be administered on the same day as of one of the following chemotherapy regimens:
	  ○ Etoposide, carboplatin, and Tecentriq (atezolizumab)
	  ▪ Cosela should be given on day 1, 2, and 3 of a 21-day cycle prior to etoposide administration for up to 4 cycles
	  ▪ Approval for this combination will be granted for 6 months
	  • More than 4 cycles of this combination will not be granted as it has not been studied beyond 4 cycles of induction therapy
	  ○ Etoposide and carboplatin
	  ▪ Cosela should be given on day 1, 2, and 3 of a 21-day cycle prior to etoposide administration until disease progression or unacceptable toxicities
	  ○ Topotecan
	  ▪ Cosela should be given on days 1-5 of a 21-day cycle prior to topotecan administration until disease progression or unacceptable toxicities

Continuation Criteria

- Requests will be reviewed per criteria every 6 months

Considerations

- Prior authorization is obtained through the CDPHP pharmacy department.

MEDICAL POLICY

Medical Policy Title	**Bone Densitometry/Bone Density Studies**
Policy Number	**6.01.05**
Current Effective Date	**November 1, 2026**
Next Review Date	**August 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Bone mineral density (BMD) testing is considered **medically necessary** when **ONE** of the following methods are used:

A. Dual-energy x-ray absorptiometry (DEXA or DXA) with or without **either** of the following:

1. Vertebral fracture assessment (VFA);
2. Trabecular bone scoring (TBS); **or**

B. Quantitative computed tomography (QCT);

C. Single-energy x-ray absorptiometry (SEXA);

D. Bone density of the heel using ultrasound; **or**

E. Quantitative ultrasound (QUS);

AND

F. **One** of the following indications with associated criteria are met:

1. Women with **ANY** of the following indications:
   a. Aged 65 years and older, regardless of additional risk factors;
   b. Estrogen-deficient women at clinical risk for osteoporosis (please refer to description section for risk factors for osteoporosis in women);
   c. Post-menopausal women who have discontinued hormone replacement therapy within the past five (5) years; **or**
2. Post-menopausal women under age 65 years with **EITHER** of the following indications:
   a. One (1) or more additional risk factors for osteoporotic fracture (please refer to description section for risk factors for osteoporosis in women); **or**
   b. At increased risk of osteoporosis, as determined by a formal clinical risk assessment tool (e.g., FRAX); **or**
3. Men with **ANY** of the following indications:

a. Men aged 50 to 70 years with clinical risk factors for osteoporotic fracture (please refer to description section for risk factors for osteoporosis in men);

b. Aged 70 years and older, regardless of additional risk factors; **or**

c. Diagnosed with prostate cancer who have received either surgical or medical androgen deprivation therapy; **or**

4. Men and post-menopausal women aged 50 years and older with **EITHER** of the following indications:

   a. Other prior fractures and low bone mass (T-score between -1.0 and -2.5 at the femoral neck, total hip, or spine); **or**

   b. Current or prior hip or vertebral fracture; **or**

5. Individuals with **ANY** of the following indications:

   a. Vertebral abnormalities, as demonstrated by an x-ray to be indicative of osteoporosis, osteopenia (low-bone mass), or vertebral fracture;

   b. Primary hyperparathyroidism;

   c. Suspected cases of secondary osteoporosis due to a broad range of disease states (e.g., hyperthyroidism, rheumatoid arthritis, or type 1 diabetes mellitus);

   d. Being monitored to assess the response to, or efficacy of an osteoporosis drug therapy approved by the U.S. Food and Drug Administration (FDA);

   e. Receiving (or expecting to receive) long-term glucocorticoid therapy (e.g., glucocorticoids in a daily dose greater than or equal to 5 mg prednisone or equivalent for greater than or equal to three (3) months);

   f. On a prescribed drug regimen (e.g., anticonvulsants, aromatase inhibitors, cytotoxic drugs, Depo-Provera contraceptive injection, or hormone replacement therapy) posing a significant risk of osteoporosis; **or**

   g. Previously diagnosed as having osteoporosis.

<u>Follow-up Testing</u>

II. Follow-up BMD testing is considered **medically appropriate** for **ANY** of the following indications:

A. Every two (2) years (at least 23 months have passed since the month the last BMD testing was performed);

B. Individuals starting on Bisphosphonate therapy, testing every three (3) years after initiation of therapy is recommended;

C. More frequently than every two (2) years, if medically necessary. Examples include, but are not limited to the following:

1. The testing is performed to monitor individuals on long-term glucocorticoid (steroid) therapy of more than three (3) months;
2. The testing is performed to obtain a confirmatory baseline (either central or peripheral) using a different BMD testing technique than was used in a patient's initial BMD test, to permit monitoring of the patient using the newer technique (e.g., if the initial test was performed using bone sonometry, and monitoring is anticipated using bone densitometry, a baseline measurement using bone densitometry is allowed); **or**

D. For women receiving estrogen replacement therapy (ERT), who should not be precluded from receiving follow-up or repeat BMD testing.

III. Osteoporosis screening procedures that are considered **investigational**, including but not limited to:

A. Pulse-echo ultrasound bone density measurement of the tibia;

B. Radiofrequency Echographic Multi Spectrometry (REMS);

C. VFA with **EITHER** of the following:

1. SEXA; **or**
2. Automated analysis of an existing Computed Tomography (CT) study

RELATED POLICIES

Corporate Medical Policy

11.01.03 Experimental or Investigational Services

POLICY GUIDELINE(S)

I. Refer to the member's subscriber contract to confirm that the member's coverage is subject to the New York State BMD testing mandate.

II. A DEXA study is representative of one (1) or more sites; therefore, a study of multiple sites should be reported and will be processed as a single unit of service.

III. This policy addresses coverage for adults only. Requests for adolescents and children will be reviewed based on diseases and risk factors that are present. Per the Bone Health and Osteoporosis Foundation (BHOF), BMD measurement is not recommended in children or adolescents.

IV. Under the Affordable Care Act, non-grandfathered plans or policies are required to cover, in-network, without cost-sharing, the preventive services recommended by the United States Preventive Services Task Force (USPSTF), including osteoporosis screening for patients identified in the above Policy Statements

V. Changes in BMD may not be detected in less than two (2) years of treatment because of the measurement technique, but a follow-up scan may be appropriate sooner in selected patients.

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

Follow-up scans can help to detect treatment failure and secondary disease.

VI. The decision to test BMD should be based on an individual's risk profile. Testing is not indicated unless the results influence a treatment decision.

VII. Whenever possible, use of central (axial skeleton) DEXA is preferred, as clinical evidence supports that this method has one of the lowest standard error rates in measurement and predictive accuracy. However, peripheral DEXA may be used as a substitute when technical problems preclude adequate imaging with a central DEXA machine or when a central DEXA machine is unavailable.

DESCRIPTION

Defining Osteoporosis by BMD

The World Health Organization has established the following definitions, based on BMD of the spine, hip or forearm by DEXA. T scores are reported as standard deviations (SD):

- Normal: T-score at -1.0 and above (within 1 SD of a young healthy adult);
- Osteopenia (low bone mass): T-score between -1 to -2.5 (1 to 2.5 SD below that of a young healthy adult);
- Osteoporosis: T-score at or below -2.5 (2.5 SD or more below that of a young healthy adult); and
- Severe osteoporosis: T-score of -2.5 or less with fragility fractures.

Although these definitions are necessary to establish the prevalence of osteoporosis, they should not be used as the sole determinant of treatment decisions.

Risk Factors for Osteoporosis in Women

There are certain symptoms, conditions, physiologic characteristics, and lifestyle factors indicative of a significant risk of osteoporosis. Per the NIH, risk factors for post-menopausal women under age 65 include, but are not limited to:

- Personal history of a non-traumatic fracture as an adult;
- Family history of osteoporosis (e.g., history of early, non-traumatic fracture in first-degree relative);
- Ethnicity - Caucasian and Asian women are at highest risk. African American and Latino women have a lower, but significant, risk;
- Poor health/frailty;
- Cigarette smoking;
- Body size – small, thin-boned women are at greater risk;
- Extended estrogen deficiency;

- Age - Risk increases with age, as bones become less dense and weaker with age;
- Eating disorders such as anorexia nervosa;
- Excessive use of alcohol;
- Low calcium and vitamin D intake (lifelong);
- Long-term use of certain medications, such as glucocorticoids;
- Sedentary lifestyle or extended bed rest; or
- Osteopenia.

Post-Menopause Definition

The American College of Obstetricians and Gynecologists defines post-menopausal as the time in a woman's life when she stops having menstrual periods - specifically, when she has gone 12 consecutive months with no menstrual period. Menopause marks the end of the reproductive years that began in puberty.

Risk Factors for Osteoporosis in Men

There are certain symptoms, conditions, physiologic characteristics or lifestyle factors indicative of a significant risk of osteoporosis. Per the NIH, risk factors for osteoporosis in men include:

- Chronic diseases that affect the kidneys, lungs, stomach, and/or intestines or alters hormone levels;
- Long-term use of certain medications, such as glucocorticoids;
- Low levels of testosterone;
- Unhealthy lifestyle habits (e.g., smoking, excessive alcohol use, low calcium intake, and inadequate physical exercise);
- Age – the older the individual, the greater the risk;
- Race – Caucasian men appear to be at particularly high risk, but all men can develop osteoporosis.

Quantitative Ultrasound (QUS)

QUS is a radiation-free bone assessment technique that uses high-frequency sound waves to evaluate bone health, most commonly at the calcaneus (heel bone). Unlike DXA, which measures bone mineral density (BMD), QUS characterizes bone tissue through its interaction with sound waves, providing information about both bone density and structural/qualitative properties. A QUS device positions the heel between two transducers — one emitting and one receiving ultrasound waves.

The calcaneus is the preferred measurement site because it consists of approximately 95% trabecular bone, has a high metabolic turnover rate, and possesses two lateral surfaces that facilitate ultrasound transmission. A limitation of QUS is it does not measure bone mineral density. The World Health Organization (WHO) diagnostic standard T-score thresholds cannot be applied to QUS values, lack of

standardization across devices, and not recommended for standalone treatment decisions or monitoring.

Pulse-echo Ultrasound

Bindex is a handheld pulse-echo ultrasound device used to measure apparent cortical bone thickness at the proximal tibia, to aid the physician in the diagnosis of osteoporosis.

Vertebral Fracture Assessment using Computed Tomography

Vertebral fracture evaluation can be performed using a pre-existing computed tomography dataset via assistive augmented intelligence. It is used for the detection of osteoporosis as evidenced by vertebral compression fractures that are below the threshold for human detection. For example, the data set from a CTA scan of the chest performed for the diagnosis of pulmonary embolism could be subsequently analyzed by an algorithm created for identification of additional findings such as subtle osteoporotic vertebral fractures.

Trabecular Bone Scoring

The trabecular bone score (TBS) is a diagnostic software tool that analyzes the internal structure of the lumbar spine bones. It is used in conjunction with dual-energy x-ray absorptiometry (DXA), which is an enhanced form of x-ray technology that is performed to measure bone mineral density (BMD). TBS uses standard DXA lumbar spine images to measure the structure of trabecular (cancellous) bone, providing additional information to be used in conjunction with BMD results in calculating fracture risk. Using a software program installed on a standard DXA computer, TBS provides an index of bone structure and quality without requiring additional radiation exposure or scan time. TBS received US FDA approval in 2012 for use as a complement to DXA analysis for the assessment of fracture risk and provides additional utility in fracture risk assessment among people with secondary causes of bone loss and fractures, such as type 2 diabetes.

REMS

REMS by Echolight is a diagnostic, non-invasive, radiation-free, office-based testing for bone density and fracture risk assessment at axial sites. It exploits all the spectral features of the native, unfiltered "raw" signals acquired during echographic scan. The algorithm automatically identifies the target bone interfaces within the sequence of the acquired echographic images, discarding "noisy" acquisitions and artifacts.

SUPPORTIVE LITERATURE

BMD Studies

While there are a number of tests available to assess bone mineral density, clinical evidence supports that DEXA of the hip or lumbar sacral spine and QCT have the lowest standard error in measurement and predictive accuracy. In addition, studies that show reduced fracture with treatment have used results from hip/spine DEXA machines.

Data from several studies showed women treated with bisphosphonates and other pharmacologic treatment benefited from reduced fractures with treatment, even if BMD did not increase. There is no

evidence from randomized, controlled trials regarding how often to monitor BMD during osteoporosis treatment. There is moderate-quality evidence suggesting that most women do not need regular monitoring.

Crandall et al (2020) conducted a cohort study assessing the need of a second BMD study approximately 3 years later after initial baseline measurement associated with improved ability to differentiate fracture risk in postmenopausal women. The study included 7,419 women mean age of 66.1 years, mean BMI 28.7 and 1,720 were non-Caucasian. During the follow-up period, 139 women experienced hip fractures, and 732 women experienced major osteoporotic fractures. When assessing the difference in the data between women who experience hip fractures and those who do not, area under the receiver operating characteristic curve (AU-ROC) values were 0.71(95% CI, 0.67-0.75) for baseline total hip BMD, 0.61 (95% CI, 0.56-0.65) for change in total hip BMD, and 0.73 (95% CI, 0.69-0.77) for the combination of baseline total hip BMD and change in total hip BMD. Femoral neck and lumbar spine BMD values had similar discrimination for hip fracture. For discrimination of major osteoporotic fracture, AU-ROC values were 0.61 (95% CI,0.59-0.63) for baseline total hip BMD, 0.53 (95% CI, 0.51-0.55) for change in total hip BMD, and 0.61 (95% CI, 0.59-0.63) for the combination of baseline total hip BMD and change in total hip BMD. Femoral neck and lumbar spine BMD values had similar ability to recognize the differences between women who experienced major osteoporotic fracture and those who did not. The change in bone density and fracture risk did not differ by subgroup, including diabetes, age, race/ethnicity, body mass index, or baseline BMD T score. Limitations for this study included that it was an observational design, and fractures were self-reported. However, strengths included prospective follow-up, and large number of participants. The researchers concluded that the evidence suggests that repeat BMD testing in postmenopausal women at three years after baseline BMD should not be routinely performed.

Vertebral Fracture Assessment using DEXA

Vertebral fractures are highly prevalent in the elderly populations, and epidemiologic studies have found that these fractures are associated with an increased risk of future spine or hip fractures independent of BMD. Only 20-30% of vertebral fractures are recognized clinically; the rest are discovered incidentally on lateral spine radiographs. Lateral spine x-rays have not been recommended as a component of risk assessment for osteoporosis, because of the cost, the radiation exposure, and the fact that the x-ray would require a separate procedure in addition to the BMD study. However, lateral spine images for vertebral fracture assessment (VFA) can be obtained using DEXA at the same time that a patient is undergoing assessment of BMD. Although VFA may be rapid and convenient, the images obtained are not of sufficient quality to establish the presence or absence of vertebral fractures. Literature suggests that densitometry may not accurately diagnose vertebral fractures in the population of interest (women with osteopenia or normal BMD). There is a lack of evidence that the test is accurate in detecting fractures among subjects without osteoporosis. Available evidence is insufficient to assess what health outcomes would result from VFA using DEXA as a screening test for osteoporosis.

Vertebral Fracture Assessment using Computed Tomography

There is currently limited research demonstrating the effectiveness of vertebral fracture assessment

using CT with assistive augmented intelligence.

Pulse-echo Ultrasound

The use of pulse-echo ultrasonometry is being promoted as a cost-effective screening option to determine appropriateness for DXA measurement. There is limited research, and no randomized, controlled trials, demonstrating the effectiveness of pulse-echo ultrasound as compared to DXA.

Algahtani et al (2025) conducted a comparative study on 168 participants, comparing the pulse-echo ultrasound versus the DXA and how they compare in acceptability, comfort, and preference. A bespoke questionnaire was given out to gather responses from the participants. The questionnaire showed that despite the discomfort from the gel application, the pulse-echo received significantly higher acceptability and comfort ratings and preferring that it is non-ionizing radiation.

Trabecular Bone Scoring

There is a lack of well-designed clinical trials including diverse populations in the peer-reviewed scientific literature addressing the impact of TBS on patient-specific health outcomes. Future prospective trials evaluating the use trabecular bone score in place of or in addition to established fracture prediction tools should report if long-term patient health outcomes are improved.

Jose et al (2021) conducted a cross-sectional single center study aimed to study the bone microarchitecture (TBS-trabecular bone score) and BMD in a total of 250 postmenopausal women with either morbid obesity, obese or non-obese. The participants were categorized based on body mass index (BMI). In the morbid obesity (BMI ≥ 35 kg/m2) group, with 85 participants was compared to 80 subjects with obesity (BMI ≥ 25–35 kg/m2) and 85 non-obese women (BMI ≤ 25 kg/m2). The BMI cut-off points for obesity were defined as per the Asia-Pacific guidelines by the WHO, suggesting lower thresholds for obesity, in order to identify individuals that are at higher risk at a lower BMI. The BMD and TBS were assessed in all subjects using a Hologic-QDR 4500-W Discovery-A DXA scanner. The mean BMD (gm/cm2) at the femoral neck in women with morbid obesity was found to be significantly lower as compared to the age-matched postmenopausal obese controls (0.723 versus 0.762). The BMD at the lumbar spine and hip showed similar trends but were not statistically significant. The bone microarchitecture was found to be significantly lower in those with morbid obesity (1.205) as compared to obesity (1.244) and non-obese (1.228). Though obesity was associated with a better bone density and bone microarchitecture in postmenopausal women, in those with morbid obesity a lower value was seen. Limitations included the lack of heterogeneity, and lacking details regarding bone reabsorption and formation markers and physical activity. Additional studies are needed to validate this study.

REMS

Al Refaie et al (2023) performed a systematic review of literature to evaluate the most recent data on the REMs technique for assessing bone mineral density. The literature obtained was from 2019 to 2023 using PubMed-Medline, Cochrane Library, ClinicalTrials.gov, and SCOPUS; cases found were cross-sectional observational studies. The authors state that the literature "confirmed diagnostic concordance between BMD values obtained using DXA and REMS. Furthermore, REMS has adequate precision and repeatability characteristics, is able to predict the risk of fragility fractures, and may be

able to overcome some of the limitations of DXA". The authors concluded that REMS could become the method of choice for the assessment of bone status in children, women of childbearing age or who are pregnant, and in several secondary osteoporosis conditions due to its good precision and replicability, transportability, and the absence of ionizing radiation. The authors did state that ongoing research is needed to better understand the role of REMS in diagnosis and follow-up in patients with osteoporosis with respect to DXA and understand what population would benefit from REMs versus DXA.

There are ongoing clinical trials but no reported results. The current studies being performed are looking at many different indications that may affect imaging for osteoporosis or may cause osteoporosis such as osteoarthritis, vitamin D deficiency, osteogenic perfecta, pregnancy. The studies are promising, showing reliable technology and the possibility to lead to earlier interventions for individuals with bone fragility. Further clinical trials are needed along with FDA approval.

PROFESSIONAL GUIDELINE(S)

Lems et al (2025) reported the results of the best practices report that made recommendations on standardization of VFA as part of standard clinical DXA assessment for osteoporosis care. The working group was endorsed by the American Association of Clinical Endocrinology (AACE), the American Society for Bone and Mineral Research (ASBMR) and representatives from 15 international societies. The recommendations state the following:

- "Ideally, VFA should be performed in all patients undergoing DXA (bone mineral density) testing."
- "If DXA access is limited, VFA should be prioritized in high-risk patients."
- "If VFA is not available on the DXA system, use conventional lateral spine X-rays to detect vertebral fractures."

The U.S. Preventive Services Task Force (USPSTF) currently recommends screening for osteoporosis with bone measurement testing to prevent osteoporotic fractures in:

- Women aged 65 years and older screen for osteoporosis with DXA BMD testing, with or without fracture risk assessment.
- Post-menopausal women younger than age 65 years with one (1) or more risk factors for osteoporosis. For women at increased risk, screen for osteoporosis with DXA BMD testing, with or without fracture risk assessment. clinical risk assessment tool.
- The current evidence is insufficient to assess the balance of benefits and harms of screening for osteoporosis in men.

The Bone Health and Osteoporosis Foundation (BHOF), formally known as The National Osteoporosis Foundation (NOF) reported theClinicians Guide to Prevention and Treatment of Osteoporosis (LeBoff et al 2022), an it includes recommendation for BMD testing for:

- Women aged 65 years and older and for men aged 70 years and older, regardless of clinical risk factors.

- Post-menopausal women in the menopausal transition and men aged 50 to 69 years based on risk profile.
- Postmenopausal women and men aged greater or equal to 50 years with a history of adult-age fracture; and
- Adults who have a condition (e.g., rheumatoid arthritis) or are taking a medication (e.g., glucocorticoids in a daily dose ≥ 5 mg prednisone or equivalent for ≥ three (3) months) associated with low bone mass or bone loss.
- BMD measurement is not recommended in children or adolescents and is not routinely indicated in healthy young men or pre-menopausal women, unless there is a significant fracture history, or there are specific risk factors for bone loss.
- Follow-up testing is recommended one (1) to two (2) years after initiating medical therapy for osteoporosis and at appropriate intervals thereafter according to clinical circumstances such as high-risk individuals (multiple fractures, older age, very low BMD).
- Vertebral fracture imaging (X-ray or DXA vertebral fracture assessment) should be performed in high-risk individuals to detect subclinical vertebral fractures. Traditionally, conventional lateral thoracic/lumbar spine X-ray has been considered the gold standard for identification of vertebral fractures and minor vertebral deformities. However, DXA-assisted vertebral fracture assessment (DXA-VFA) is emerging as an alternative to radiography for its convenience, low cost, and minimal radiation exposure. Recently performed MRI or CT imaging studies done for other purposes can and should also be evaluated for presence of vertebral fractures or evidence of vertebral deformity.

American Association of Clinical Endocrinologists/American College of Endocrinology Clinical Practice Guidelines for the Diagnosis and Treatment of Postmenopausal Osteoporosis (Camacho 2020):

- An update to the guidelines in 2020 includes stratification of women with osteoporosis into high-risk and very-high-risk features to drive choice and duration of initial therapy.

The Endocrine Society Clinical Practice Guideline: Osteoporosis in Men (2012) recommends:

- Testing higher-risk men (men age greater than or equal to 70 years and men aged 50 to 69 years who have risk factors [e.g., low body weight, prior fracture as an adult, smoking, etc.]) using central dual-energy x-ray absorptiometry.
- The guideline suggests measuring forearm DXA (1/3 or 33% radius) when spine or hip BMD cannot be interpreted and for men with hyperparathyroidism or receiving androgen deprivation therapy for prostate cancer.

In 2023 a the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO), the International Osteoporosis Foundation (under the auspices of WHO Collaborating Center for Epidemiology of Musculoskeletal Health and Aging) conducted a systematic review on the clinical use of trabecular bone score. The four topics that were reviewed consisted of the use of TBS in fracture risk prediction, treatment initiation and assessing response to pharmacological interventions in postmenopausal osteoporosis, fracture risk in secondary

osteoporosis and for assessing response to pharmacological therapies in secondary osteoporosis. The recommendations are as follows:

- TBS should be used in conjunction with BMD and clinical risk factors (strongly recommended).
- TBS results should be interpreted within clinical context of the patient (strongly recommended).
- Reduction in TBS is observed in most secondary osteoporosis-related diseases, and predicts fracture risk in type 2 diabetes, chronic kidney disease, patients treated with glucocorticoids, rheumatological diseases and it is relatively unaffected by spinal changes (strongly recommended).
- TBS adds value when used with BMD in monitoring skeletal effects of aromatase inhibitors, glucocorticoids and response to antiosteoporosis therapy across both primary and secondary osteoporosis (strongly recommended).

REGULATORY STATUS

The United States Food and Drug Administration (FDA) regulates bone mineral density devices as medical devices. All [device] including related components require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2026 Jul 17]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most serious type of recalls on our website by the date that the FDA posts the information on our website. Available from: Medical Device Recalls | FDA [accessed 2026 Jul 17]

The New York Insurance Law mandates that coverage be provided for bone density tests, as well as prescription drugs and devices that are approved by the FDA, for the detection and treatment of osteoporosis. The law provides that individuals qualifying for coverage shall, at a minimum, include individuals who have any of the following:

- A previous diagnosis or family history of osteoporosis;
- Symptoms or a condition indicative of the presence or significant risk of osteoporosis;
- A prescribed drug regimen posing a significant risk of osteoporosis;
- Lifestyle factors posing a significant risk of osteoporosis; or
- Age, gender, and/or physiological characteristics posing a significant risk of osteoporosis.

Several DEXA central bone densitometers have been approved by the FDA, such as the Norland XR 46 DXA (Central) Bone Densitometer. Several bone ultrasonometers have been cleared for marketing by the FDA, such as Myriad's Soundscan (approved May 1998) and Hologic's Sahara Clinical Bone Sonometer (approved March 1998). To perform VFA on DEXA devices, additional software is needed and must also have Section 510(k) marketing clearance from the FDA.

Bone Index Finland, Ltd. received Section 510(k) approval from the FDA in May 2016 for Bindex BI-100 and Bindex BI-2 in January 2017.

CODE(S)

CPT Codes

Code	Description
76977	Ultrasound bone density measurement and interpretation, peripheral site(s), any method
76999*	Unlisted ultrasound procedure (e.g., diagnostic, interventional) (*Consider E/I when used to report pulse-echo ultrasound for bone density measurement testing.)
77078	Computed tomography, bone mineral density study, 1 or more sites, axial skeleton (e.g., hips, pelvis, spine)
77080	Dual-energy X-ray absorptiometry (DXA), bone density study, 1 or more sites; axial skeleton (e.g., hips, pelvis, spine)
77081	Dual-energy X-ray absorptiometry (DXA), bone density study, 1 or more sites; appendicular skeleton (peripheral) (e.g., radius, wrist, heel)
77085	Dual-energy X-ray absorptiometry (DXA), bone density study, 1 or more sites; axial skeleton (e.g., hips, pelvis, spine), including vertebral fracture assessment
77086	Vertebral fracture assessment via dual-energy X-ray absorptiometry (DXA)
77089	Trabecular bone score (TBS), structural condition of the bone microarchitecture; using dual X-ray absorptiometry (DXA) or other imaging data on gray-scale variogram, calculation, with interpretation and report on fracture-risk
77090	technical preparation and transmission of data for analysis to be performed elsewhere
77091	technical calculation only

Code	Description
77092	interpretation and report on fracture-risk only by other qualified health care professional
0554T (E/I)	Bone strength and fracture risk using finite element analysis of functional data, and bone-mineral density, utilizing data from a computed tomography scan; retrieval and transmission of the scan data, assessment of bone strength and fracture risk and bone mineral density, interpretation and report
0555T (E/I)	retrieval and transmission of the scan data
0556T (E/I)	assessment of bone strength and fracture risk and bone mineral density
0557T (E/I)	interpretation and report
0691T (E/I)	Automated analysis of an existing computed tomography study for vertebral fracture(s), including assessment of bone density when performed, data preparation, interpretation, and report
0743T (E/I)	Bone strength and fracture risk using finite element analysis of functional data and bone-mineral density (BMD), with concurrent vertebral fracture assessment, utilizing data from a computed tomography scan, retrieval and transmission of the scan data, measurement of bone strength and BMD and classification of any vertebral fractures, with overall fracture risk assessment, interpretation and report
0815T (E/I)	Ultrasound-based radiofrequency echographic multi-spectrometry (REMS), bone-density study and fracture-risk assessment, 1 or more sites, hips, pelvis, or spine

MEDICAL POLICY

Medical Policy Title	**Breast Reconstruction Surgery and Prophylactic Breast Cancer Risk-Reducing Mastectomy**
Policy Number	**10.01.01**
Current Effective Date	**September 1, 2026**
Next Review Date	**August 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Reconstructive breast surgery during or after surgical mastectomy, including partial mastectomy (e.g., lumpectomy, segmentectomy, quadrantectomy) for benign or malignant disease, is considered **medically appropriate**, and may include the following services:

   A. All stages of reconstruction, including, but not limited to:

      1. Breast implants;
      2. Abdominal flap reconstruction;
      3. Chest wall reconstruction;
      4. Nipple/areola reconstruction and tattooing; and
      5. Surgery for symmetry of the contralateral (opposite) breast;

   B. Basic breast prosthetic(s) and mastectomy bras;

   C. Treatment of physical complications of mastectomy, including lymphedema (in accordance with Corporate Medical Policy #1.01.17 Powered Compression Devices/Lymphedema Pumps).

II. A risk-reducing mastectomy is considered a **medically appropriate** prophylactic treatment for individuals with **ANY** of the following high-risk breast cancer factors:

   A. Lobular carcinoma in situ;

   B. A known BRCA1 or BRCA2 variant;

   C. Another gene variant associated with high risk (e.g., TP53 [Li-Fraumeni syndrome], PTEN [Cowden syndrome, Bannayan-Riley-Ruvalcaba syndrome], CDH1, STK11, and PALB2;

   D. Received radiotherapy to the chest between the ages of 10 and 30 years (e.g., Hodgkin's disease).

III. The following techniques are considered **medically appropriate** alternatives to a medically appropriate risk-reducing conventional mastectomy:

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

A. A skin-sparing mastectomy;

B. A nipple-sparing mastectomy;

C. A two-stage procedure including an oncoplastic breast reduction followed by a risk-reducing mastectomy and breast reconstruction.

RELATED POLICIES

7.01.11 Cosmetic and Reconstructive Procedures

7.01.35 Bioengineered Tissue Products for Wound Treatment and Surgical Interventions

7.01.39 Reduction Mammaplasty (Mammoplasty)

POLICY GUIDELINE(S)

I. The Federal Women's Health and Cancer Rights Act (WHCRA) of 1998, as well as the New York Insurance Law, mandate coverage of all stages of reconstructive surgery for individuals who have or have not been diagnosed with breast cancer, in the manner determined by the attending physician and the patient to be appropriate which can include surgery and reconstruction of the contralateral breast to produce symmetrical appearance, chest wall reconstruction, prosthesis, treatment of physical complications following mastectomy and prophylactic mastectomies for all group health plans, whether insured or self-funded, that provide medical and surgical benefits.

II. It is recommended that all individuals considering risk-based mastectomy have counseling provided by a health professional (other than the operating surgeon) who is skilled in assessing cancer risk. This discussion should include an explanation of the risks and benefits of various screening and treatment options (e.g., increased surveillance or chemoprevention).

DESCRIPTION

Reconstructive breast surgery is a surgical procedure that is designed to restore the normal appearance of the breast after surgery, accidental injury, or trauma. The nature and extent of the reconstructive breast surgery depends upon the initial surgery or treatment that an individual receives to remove all or a portion of a breast.

The reconstructive surgery may be performed in a single stage or several stages/phases and either during or after a surgical procedure to remove breast tissue. Reconstruction may include, but is not limited to:

- Insertion of saline or silicone filled prosthetic implants;
- Extensive flap reconstruction (e.g., deep inferior epigastric perforator [DIEP] flap, gluteal artery perforator [GAP] flap, latissimus dorsi flap, superficial inferior epigastric artery [SIEA]

flap, transverse rectus abdominus myocutaneous [TRAM] flap);

- Chest wall reconstruction;
- Nipple/areola reconstruction and tattooing;
- Surgery for symmetry of the contralateral (opposite) breast.

Conventional mastectomy is a surgical procedure that involves removing the entirety of the breast tissue, skin overlying the breast, and the nipple-areola complex. A risk-reducing mastectomy, also referred to as a preventative or prophylactic mastectomy, is the surgical removal of both breasts for the purpose of reducing cancer risk and is meant for individuals who are considered very high risk. The surgery may be performed as a total mastectomy, where the nipple and areola are removed or via a nipple-sparing technique that preserves the nipple and areola. Total mastectomy provides a vaguely higher level of risk reduction (as high as 95% in women who have disease causing variants [BRCA 1 /BRCA2]) compared to nipple-sparing mastectomy, which allows for more natural-looking breasts after reconstruction.

SUPPORTIVE LITERATURE

Wong et al (2017) updated and examined national trends in contralateral prophylactic mastectomy (CPM) and examined if survival differed for invasive breast cancer patients based on hormone receptor status and age. These investigators identified women diagnosed with unilateral stage I to III breast cancer between 1998 and 2012 within the Surveillance, Epidemiology, and End Results registry. They compared characteristics and temporal trends between patients undergoing breast-conserving surgery, unilateral mastectomy, and CPM. Of 496,488 women diagnosed with unilateral invasive breast cancer, 59.6% underwent breast-conserving surgery, 33.4% underwent unilateral mastectomy, and 7.0% underwent CPM. Overall, the proportion of women undergoing CPM increased from 3.9% in 2002 to 12.7% in 2012 ($p < 0.001$). Reconstructive surgery was performed in 48.3% of CPM patients compared with only 16.0% of unilateral mastectomy patients, with rates of reconstruction with CPM rising from 35.3% in 2002 to 55.4% in 2012 ($p < 0.001$). When compared with breast-conserving therapy, these researchers found no significant improvement in breast cancer-specific survival (BCSS) or overall survival (OS) for women undergoing CPM (BCSS: HR 1.08, 95% CI: 1.01 to 1.16; OS: HR 1.08, 95% CI: 1.03 to 1.14), regardless of hormone receptor status or age. The authors concluded that the use of CPM more than tripled during the study period despite evidence suggesting no survival benefit over breast conservation. They stated that further examination on how to optimally counsel women about surgical options is needed.

A Cochrane review by Carbine et al (2018) examined the impact of risk-reducing mastectomy on mortality and other health outcomes. Reviewers did not identify any randomized controlled trials. Sixty-one observational studies with some methodologic limitations were identified. The studies presented data on 15,077 individuals with a wide range of risk factors for breast cancer who underwent a risk-reducing mastectomy. Studies on the incidence of breast cancer and disease-specific mortality (n=21) reported reductions in both after a bilateral risk-reducing mastectomy, particularly for those with BRCA1 or BRCA2 variants.

The previously summarized Cochrane review by Carbine et al (2018) also assessed various outcomes, including mortality and disease-free survival, among individuals who received a contralateral risk-reducing mastectomy. Twenty-six observational studies assessed outcomes in these individuals. While results showed a reduced incidence of CBC among those who received a contralateral risk-reducing mastectomy, results on disease-specific mortality were inconsistent. Seven of the included studies showed no survival advantage. One additional study showed an improvement in all-cause mortality associated with contralateral risk-reducing mastectomy; however, significance was lost after adjustment for bilateral risk-reducing salpingo-oophorectomy. The authors attributed the variability in mortality findings, in part, to selection bias, since younger, healthier individuals may be more likely to opt for contralateral risk-reducing mastectomy.

Filipe et al (2022) performed a systematic review and meta-analysis that compared the postoperative complication rate of robotic nipple-sparring mastectomy (RNSM) to nipple-sparring mastectomy (NSM). The primary outcome was determining the overall postoperative complication rate of traditional NSM and RNSM. Secondary outcomes were comparing the specific postoperative complication rates: implant loss, hematoma, (flap)necrosis, infection, and seroma. Forty-nine studies containing 13,886 cases of (R)NSM were included. No statistically significant differences were found regarding postoperative complications (RNSM 3.9%, NSM 7.0%, $p = 0.070$), postoperative implant loss (RNSM 4.1%, NSM 3.2%, $p = 0.523$), hematomas (RNSM 4.3%, NSM 2.0%, $p = 0.059$), necrosis (RNSM 4.3%, NSM 7.4%, $p = 0.230$), infection (RNSM 8.3%, NSM 4.0%, $p = 0.054$) or seromas (RNSM 3.0%, NSM 2.0%, $p = 0.421$). Overall, there are no statistically significant differences in complication rates between NSM and RNSM.

Schelletter et al (2025) conducted a systematic review and meta-analysis aimed to provide a comprehensive, quantitative assessment on the risk associated with implant-based reconstruction in CPM versus therapeutic mastectomy (TM). Five studies were included in the final analysis, representing 3543 patients who underwent 6401 mastectomies (3260 TM and 3141 CPM), followed by prosthetic breast reconstruction including tissue expanders and direct-to-implant procedures. Reconstructions after TM were associated with a statistically significantly higher risk of postoperative infections (OR = 2.03 [95% CI: 1.50 – 2.73]) and explanation rates (OR = 2.41 [95% CI: 1.77 – 3.28]). No significant differences were observed between the two groups in the occurrence of hematoma, seroma, necrosis, and capsular contracture. Authors concluded that implant-based breast reconstruction after CPM demonstrates a lower risk of postoperative complications compared with TM.

PROFESSIONAL GUIDELINE(S)

NCCN Guidelines V.3.2026 Genetic/Familial High-Risk Assessment: Breast, Ovarian, and Pancreatic recommends that the option of risk reducing mastectomy (RRM) be discussed for carriers of the following genetic variants: BRCA-Pathogenic/Likely Pathogenic Variant-Positive, CDH1, PALB2, STK11, and Li-Fraumeni. For those with clinical Cowden syndrome/PTEN hamartoma tumor syndrome, consideration of risk-reducing surgery should be based on family history. Counseling should include a discussion regarding degree of protection, reconstruction options, and risks.

In 2021, The American College of Medical Genetics (ACMG) published a clinical practice resource for individuals with germline PALB2 variants. PALB2 is a major cancer susceptibility gene, and given this, The ACMG recommends that "Risk-reducing mastectomy can be considered as an option. The decision should be guided by a personalized risk assessment." In 2020, The American Society of Breast Surgeons (ASBrS) published a consensus statement on contralateral prophylactic mastectomy (CPM) (Boughey et al), concluding that CPM should be considered for those at significant risk of contralateral breast cancer who are documented BRCA1/2 carriers, strong family history where patient has not undergone genetic testing, and history of mantle chest radiation before age 30 years. CPM for those at lower risk of contralateral breast cancer but whom should be considered for CPM include Gene carriers of non-BRCA genes (e.g., CHECK-2, PALB2, p53, CDH1), strong family history where patient is BRCA negative and no known BRCA family member. CPM should additionally be considered for other reasons including to limit contralateral breast surveillance, improve reconstructed breast symmetry, manage risk aversion, to manage extreme anxiety. ASBrS discourages CPM in average-risk women with unilateral breast cancer, women with advanced index cancer, women at high-risk for surgical complications, women who have tested BRCA negative with a family of BRCA positive carriers, and for male breast cancer, including BRCA carriers.

The American Society of Clinical Oncology, American Society for Radiation Oncology, and Society of Surgical Oncology published joint guidelines for the management of hereditary breast cancer (Tung et al 2020). The guidelines include the following recommendations related to breast conserving surgery (BCS) which are based on formal consensus:

I. The following factors should be considered for assessing risk of contralateral breast cancer (CBC) and role of risk-reducing mastectomy in BRCA1/2 mutation carriers: age at diagnosis (the strongest predictor of future CBC), family history of breast cancer, overall prognosis from this or other cancers (e.g., ovarian), ability of patient to undergo appropriate breast surveillance (magnetic resonance imaging [MRI]), comorbidities, and life expectancy (Evidence quality: low; Strength of recommendation: moderate);

II. Patients with newly diagnosed breast cancer who have a mutation in a moderate-penetrance breast cancer susceptibility gene, mutation status alone should not determine local therapy decisions for the index tumor or contralateral risk-reducing mastectomy (CRRM) (Evidence quality: low, Strength of recommendation: moderate);

III. In patients with breast cancer with a mutation in a moderate-penetrance breast cancer susceptibility gene, BCT should be offered to those for whom BCT is an appropriate treatment option. There is a lack of data regarding ipsilateral breast cancer events after BCT among patients with moderate-risk mutations (Evidence quality: low; Strength of recommendation: moderate);

IV. For women with newly diagnosed breast cancer undergoing mastectomy who have a deleterious mutation in BRCA1/2, nipple-sparing mastectomy is a reasonable oncologic approach to consider in appropriately selected patients (Evidence quality: intermediate; Strength of recommendation: moderate);

V. For women with newly diagnosed breast cancer undergoing mastectomy who have a deleterious mutation in a moderate penetrance gene, nipple-sparing mastectomy is a reasonable oncologic approach to consider in appropriately selected patients (Evidence quality: low; strength of recommendation: moderate);

VI. Surgical management of the index malignancy (including BCT, ipsilateral therapeutic and contralateral risk-reducing mastectomy in BRCA1/BRCA 2 mutation carriers should be discussed (Evidence quality: intermediate, strength of recommendation: strong);

VII. For women with breast cancer who have a BRCA1/BRCA 2 mutation and who have been treated or are being treated with unilateral mastectomy, CRRM should be offered. CRRM is associated with a decreased risk of CBC; there is insufficient evidence for improved survival. The following factors should be considered for assessing risk of CBC and role of risk-reducing mastectomy: age at diagnosis (the strongest predictor of future CBC), family history of breast cancer, overall prognosis from this or other cancers (e.g., ovarian), ability of patient to undergo appropriate breast surveillance (MRI), comorbidities, and life expectancy (Evidence quality: intermediate; strength of recommendation: moderate).

VIII. For women with breast cancer who have a mutation in a moderate-penetrance breast cancer predisposition gene and who have been treated or are being treated with unilateral mastectomy, the decision regarding CRRM should not be based predominantly on mutation status. Additional factors that predict CBC such as age at diagnosis and family history should be considered, as they are in all cases. The impact of CRRM on decreasing risk of CBC is dependent on the risk of CBC for each individual gene. Data regarding the risk of CBC resulting from moderate-penetrance genes are limited (Type: formal consensus; Evidence quality: low; strength of recommendation: moderate);

IX. For patients with breast cancer with a deleterious germline BRCA1/2 mutation interested in CRRM, physicians should discuss the option of nipple-sparing mastectomy as a reasonable oncologic option (Type: formal consensus; Evidence quality: intermediate; strength of recommendation: strong).

X. For patients with breast cancer with a mutation in a moderate-penetrance gene who are interested in CRRM, physicians should discuss the option of nipple-sparing mastectomy as a reasonable oncologic option (Evidence quality: low; strength of recommendation: moderate).

REGULATORY STATUS

The U.S. Food and Drug Administration (FDA) regulates breast reconstruction implants as medical devices. All breast reconstruction implants require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2026 June 30]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most

serious type of recalls. Available from: Medical Device Recalls | FDA [accessed 2026 June 30]

CODE(S)

- Codes may not be covered under all circumstances.

- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
11920	Tattooing, intradermal introduction of insoluble opaque pigments to correct color defects of skin, including micropigmentation; 6.0 sq cm or less
11921	6.1 to 20.0 sq cm
11922	each additional 20.0 sq cm, or part thereof (List separately in addition to code for primary procedure)
13100	Repair, complex, trunk; 1.1 cm to 2.5 cm
13101	Repair, complex, trunk; 2.6 cm to 7.5 cm
14000	Adjacent tissue transfer or rearrangement, trunk; defect 10 sq cm or less
14001	Adjacent tissue transfer or rearrangement, trunk; defect 10.1 sq cm to 30 sq cm
14301	Adjacent tissue transfer or rearrangement, any area; defect 30.1 sq cm to 60.0 sq cm
15650	Transfer, intermediate, of any pedicle flap (abdomen to wrist, Walking tube), any location
15738	Muscle, myocutaneous, or fasciocutaneous flap; lower extremity
15740	Flap; island pedicle requiring identification and dissection of an anatomically named axial vessel
15770	Graft; derma-fat-fascia
15771	Grafting of autologous fat harvested by liposuction technique to trunk, breasts, scalp, arms, and/or legs; 50cc or less injectate
15772	each additional 50cc injectate or part thereof (List separately in addition to code for primary procedure)
19316	Mastopexy

Code	Description
19318	Breast reduction
19325	Breast augmentation with implant
19328	Removal of intact breast implant
19330	Removal of ruptured breast implant, including implant contents (e.g., saline, silicone gel)
19340	Insertion of breast implant on same day of mastectomy (i.e., immediate)
19342	Insertion or replacement of breast implant on separate day from mastectomy
19350	Nipple/areola reconstruction
19355	Correction of inverted nipples
19357	Tissue expander placement in breast reconstruction, including subsequent expansion(s)
19361	Breast reconstruction with latissimus dorsi flap
19364	Breast reconstruction with free flap (e.g. fTRAM, DIEP, SIEA, GAP flap)
19367	Breast reconstruction; with single pedicled transverse rectus abdominis myocutaneous (TRAM) flap
19368	requiring separate microvascular anastomosis (supercharging)
19369	Breast reconstruction; with bipedicled transverse rectus abdominis myocutaneous (TRAM) flap
19370	Revision of peri-implant capsule, breast, including capsulotomy capsulorrhaphy, and/or partial capsulectomy
19371	Peri-implant capsulectomy, breast, complete, including removal of all intracapsular contents
19380	Revision of reconstructed breast (e.g., significant removal of tissue, re-advancement and/or re-inset of flaps in autologous reconstruction or significant capsular revision combined with soft tissue excision in implant-based reconstruction
19396	Preparation of moulage for custom breast implant
19499	Unlisted procedure, breast
21601	Excision of chest wall tumor including rib(s)
21602	Excision of chest wall tumor involving rib(s) with plastic reconstruction, without mediastinal lymphadenectomy

Code	Description
21603	Excision of chest wall tumor including rib(s) with plastic reconstruction, with mediastinal lymphadenectomy
21740	Reconstructive repair of pectus excavatum or carinatum; open
21742	Reconstructive repair of pectus excavatum or carinatum minimally invasive approach (Nuss procedure), without thoracoscopy
21743	Reconstructive repair of pectus excavatum or carinatum minimally invasive approach (Nuss procedure), with thoracoscopy

MEDICAL POLICY

Medical Policy Title	**Bulking Agents for Treatment of Urinary or Fecal Incontinence**
Policy Number	**7.01.22**
Current Effective Date	**September 1, 2026**
Next Review Date	**March 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service.

POLICY STATEMENT(S)

Urinary Incontinence

I. Urethral bulking agents for the treatment of urinary incontinence may be considered **medically appropriate** if approved by the U.S. Food and Drug Administration (FDA) and meet the required criteria for the following indications:

   A. Collagen implants when the following criteria are met:

      1. **BOTH** of the following criteria:

         a. Stress incontinence due to urethral sphincter dysfunction; **and**

         b. Unresponsive to conservative therapy;

         AND

      2. **ONE** of the following indications:

         a. Patients with congenital sphincter weakness secondary to conditions such as myelomeningocele or epispadias;

         b. Patients with acquired sphincter weakness secondary to spinal cord lesion;

         c. Biological male patients following trauma, including prostatectomy and/or radiation; **or**

         d. Biological female patients without urethral hypermobility and with abdominal leak point pressure of 100 cm H_2O or less.

   B. Bulking agents when the following criteria are met:

      1. **ALL** of the following criteria:

         a. Treatment of stress incontinence due to intrinsic sphincter deficiency (ISD);

         b. Only in biological female patients; **and**

         c. Unresponsive to conservative therapy;

         AND

2. **ANY** of the following bulking agents, including but not limited to:
    a. Carbon-coated beads (Durasphere);
    b. Polyacrylamide hydrogel (Bulkamid);
    c. Spherical particles of calcium hydroxyapatite (Coaptite); **or**
    d. Polydimethylsiloxane (silicone elastomer) particles (Macroplastique).

II. Urethral bulking agents are considered **not medically necessary** in the treatment of other types of urinary incontinence including, but not limited to, the following:
    A. Urinary retention with overflow incontinence;
    B. Ectopic ureter;
    C. Neurogenic bladder dysfunction;
    D. Urinary fistulas;
    E. Psychogenic incontinence.

III. Additional Durasphere implants are considered **not medically necessary** when incontinence does not improve with five (5) separate injection sessions.

IV. Urethral bulking agents are considered **investigational** for the treatment of urinary stress incontinence including, but not limited to, **ANY** of the following:
    A. Polytetrafluoroethylene (Teflon);
    B. Autologous cellular therapy (e.g., myoblasts, fibroblasts, muscle-derived stem cells, adipose-derived stem cells);
    C. Microballoons (UroVive).

Fecal Incontinence

V. Perianal bulking agents to treat fecal incontinence (FI) are considered **investigational**.

POLICY GUIDELINE(S)

I. Use of Durasphere is restricted to prescription use by doctors trained in cystoscope use who have completed the appropriate implant training program.

DESCRIPTION

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

Intrinsic Sphincter Deficiency

One physiologic cause of urinary incontinence is intrinsic sphincter deficiency (ISD). ISD describes a condition in which the urethral sphincter has been damaged by surgery, neurological disorders, or trauma. The result is sphincter incompetence and urinary leakage.

There are two types of ISD:

- Total ISD is characterized by constant involuntary dripping of urine from the urethra day and night without bladder distention, as determined by physical examination of the abdomen and measurement of residual urine.
- Partial sphincter deficiency, also known as stress incontinence, affects patients who may experience involuntary loss of urine when coughing, bending, lifting or performing any maneuver that increases transabdominal pressure.

Urethral Bulking Agents

Urethral bulking agents are substances that have been developed for use in the treatment of stress incontinence due to ISD. These substances are injected at the area of the bladder neck and proximal urethra. The increased bulk caused by these substances enhances urethral resistance to the outflow of urine, thus reducing urine leakage. Urethral bulking agents may be injected over a course of several treatments until the desired effect is achieved. The procedure for injecting urethral-bulking agents is performed either in the doctor's office or the outpatient department of a hospital.

Pyrolytic Carbon-Coated Beads (Durasphere)

Datasphere are indicated for use in the treatment of adult women with stress urinary incontinence due to ISD. Carbon beads do not require skin testing, as there is no associated antigenicity. Durasphere is injected sub-mucosal at the bladder neck in females. The final bulking result is derived from the combination of the carbon-coated beads and the body's own collagen.

Coaptite

Coaptite is an injectable implant composed of spherical particles of calcium hydroxyapatite. It is indicated for the treatment of stress urinary incontinence due to (ISD) in adult females.

Bulkamid

Bulkamid is a thick, permanent gel containing 2.5% cross-linked polyacrylamide and 97.5% apyrogenic water. It is injected into the wall of the urethra near the bladder to treat women who have stress urinary incontinence or stress predominant, mixed incontinence due to ISD.

Macroplastique

Macroplastique is an injectable soft-tissue urethral bulking agent for treating stress urinary incontinence primarily due to intrinsic sphincter deficiency. Macroplastique is made up of a water-soluble gel (polyvinylpyrrolidone) that is absorbed and removed from the body in urine; the synthetic, rubber-like, silicone elastomer implant material (cross-linked polydimethylsiloxane) is permanent and not absorbed by the body. The silicone elastomer causes the bulking effect around the urethra after

implantation.

Bulking agents injected into the anal canal have been proposed for treating fecal incontinence associated with internal anal sphincter (IAS) dysfunction. The bulking agent is injected into the submucosa of the anal canal to increase tissue bulk in the area, which narrows the opening of the anus. Current treatment options for fecal incontinence include conservative measures, e.g., dietary changes, pharmacotherapy, pelvic floor muscle exercises, sacral nerve stimulation, and surgical interventions to correct an underlying problem.

SUPPORTIVE LITERATURE

Urinary Incontinence

Clinical trials investigating the safety and efficacy of Durasphere have shown that they have improved the net health outcomes of patients in the short term by achieving dryness or significant improvements in the symptoms of incontinence and provided benefits comparable to alternative treatments such as surgery.

Braga et al (2022) conducted a systematic review, and meta-analysis on 11 articles to summarize the literature findings on the use of urethral bulking agents to manage recurrent stress urinary incontinence after failure of a mid-urethral sling. The overall cure and improvement rate ranged from 64% to 85% in the included studies, with a pooled value of 75%, compared with pooled failure and re-operation rates of 32% and 25%, respectively. A sub-group analysis was performed using bulking agents, bulkmamid and macroplastique. The pooled values of the cure and improvement rate were 84% and 80% for both of the bulking agents. While the study shows promise of using urethral bulking agents after failed mid-urethral sling, they suggest that further studies be completed.

Capobianco et al (2019) conducted a systematic review, and meta-analysis to evaluate the efficacy and the effectiveness, safety and tolerability of urethral bulking agents (UBAs) in women with mixed or stress urinary incontinence. Out of 42 full articles only 21 were selected. The most frequently administered bulking agents were Bulkmamid and macroplastique, followed by urolastic, Macroplastique Implantation System (MIS) and durasphere. The improvement rate was higher than 50 %, with an estimated 57 % after a follow-up of>1 year. The outcome cure/dryness ranged from 9.1% to 56.7 %. The treatment success rate, assessed with different tools, ranged from 32.7% to 93.3%. The pooled objective treatment success rate was 7.0 % and 46.0 % in patients receiving follow-up ≤12 and>12 months, retrospectively. There were several limitations based on quality, including the risk of selection bias. The study concluded that optimal injection technique has yet to be standardized. Overall, rates of complications that were associated with UBAs are low; however, long-term implications of permanent UBAs in the periurethral milieu are unknown.

Though autologous fat injections do not require FDA approval, results of clinical studies have shown poor health outcomes associated with reabsorption and fibrotic ingrowth.

Fecal Incontinence

Knowles et al (2023), conducted a multicenter, prospective, non-randomized study of 48 participants. The objective of the study was to examine the safety and efficacy of iltamiocel, an investigational

cellular therapy of autologous muscle-derived cells, as treatment for FI. Each participant was injected with a single dose of iltamiocel. No serious adverse effects and only one product-related adverse effect of inflammation at the injection site were reported. A ≥ 50% reduction in FI episodes was observed in 53.7% of participants, and 24.4% had complete restoration of continence. Symptom severity and quality of life improved with mean Cleveland Clinic Incontinence Score reduction (-2.9; 95% CI: −3.7, −2.1), and Fecal Incontinence Quality of Life increased (2.2; 95% CI:1.4, 2.9). No significant changes were detected in anorectal manometry measurements. Historically, episiotomy was significantly associated with treatment response in multivariate analysis. The administration of iltamiocel cellular therapy is safe. Iltamiocel shows promise for significantly improving fecal incontinence symptoms and quality of life.

Maeda et al (2013), in a Cochrane Review, determined the effectiveness of perianal injection of bulking agents for the treatment of fecal incontinence in adults. Five eligible randomized trials with a total of 382 patients were identified. Four of the trials were at an uncertain or high risk of bias. Most trials reported a short-term benefit from injections regardless of the material used, including placebo saline injection. One study demonstrated dextranomer in stabilized hyaluronic acid (NASHA Dx) to be more effective than sham injection, but with more adverse effects. Another study comparing silicone material (PTQ) to saline injections was too small to demonstrate a clinical benefit compared to the control injection of normal saline. A silicone biomaterial (PTQ) was shown to provide some advantages and was safer in treating fecal incontinence than carbon coated beads (Durasphere) in the short term. Similarly, there were short-term benefits from injections delivered under ultrasound guidance compared with digital guidance. No evidence on long-term outcomes was available, and further conclusions were not warranted from the available data. None of the studies reported patient evaluation of outcomes, and, thus, it is difficult to gauge whether the improvement in incontinence scores matched practical symptom improvements that mattered to the patients. The authors concluded that one large, randomized, controlled trial has shown that this form of treatment using dextranomer in stabilized hyaluronic acid (NASHA Dx) improves continence for a little over half of patients in the short term. However, the number of identified trials was limited, and most had methodological weaknesses.

PROFESSIONAL GUIDELINE(S)

Urinary Incontinence

American Urological Association (AUA) Guidelines (2017; amended 2023) for the Surgical Treatment of Female Stress Urinary Incontinence (SUI):

- "Physicians should not offer stem cell therapy for stress incontinent patients outside of investigative protocols." (Expert Opinion).
- Clinicians should counsel index patients considering surgery for SUI regarding the efficacy and safety of bulking agents (Strong recommendation; Evidence Level: Grade A).

American Urogynecologic Society 2024 Clinical Practice Statement in Urethral Bulking recommend the following:

- "Urethral bulking agents are indicated in cases of stress urinary incontinence (SUI), and that intrinsic sphincter deficiency is not predictive of patient outcomes" (Grade B evidence; strength [SOR]: strong recommendation).
- "Urethral bulking agents may be considered for initial management of SUI, however the grade of evidence and strength of the recommendation were weaker" (Grade C evidence; SOR: recommendation).

Fecal Incontinence

The American Society of Colon and Rectal Surgeons Clinical Practice Guidelines for the Management Fecal Incontinence (Bordeianou 2023) state that injection of biocompatible bulking agents into the anal canal is not routinely recommended for the treatment of FI.

American Gastroenterological Association 2017 Clinical Practice Update for Surgical Interventions and the Use of Device-Aided Therapy for the Treatment of Fecal Incontinence and Defecatory Disorders suggest the following:

- "Perianal bulking agents such as intra-anal injection of dextranomor may be considered when conservative measures and biofeedback therapy fail."

REGULATORY STATUS

Urinary Incontinence

Cross-linked collagen, carbon-coated beads (Durasphere), Coaptite, Bulkamid, and Macroplastique have been approved by the FDA, but only for the treatment of urinary stress incontinence due to ISD. Durasphere, Coaptite, Bulkamid, and Macroplastique are approved only for use in biologic females. Other synthetic urethral bulking agents do not have FDA approval.

The U.S. Food and Drug Administration (FDA) regulates [device] as medical devices. All [device] including related components require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2026 Feb 05]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most serious type of recalls. Available from: Medical Device Recalls | FDA [accessed 2026 Feb 05]

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
0963T (E/I)	Anoscopy with directed submucosal injection of bulking agent into anal canal (Effective 07/01/25)
0999T (E/I)	Autologous muscle cell therapy, harvesting of muscle progenitor cells, including ultrasound guidance, when performed (Effective 01/01/26)
1000T (E/I)	Autologous muscle cell therapy, administration of muscle progenitor cells into the urethral sphincter, including cystoscopy and post-void residual ultrasound, when performed (Effective 01/01/26)
1001T (E/I)	Autologous muscle cell therapy, injection of muscle progenitor cells into the external anal sphincter, including ultrasound guidance, when performed (Effective 01/01/26)
46999 (*E/I)	Unlisted procedure, anus (*E/I when used for Fecal incontinence ICD10 code range R15.0-R15.9)
51715	Endoscopic injection of implant material into the submucosal tissues of the urethra and/or bladder neck

Disclaimer Notice

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgment when deciding the most appropriate care to enrollees. The CDPHP coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

Background

Thrombotic thrombocytopenia purpura (TTP) is a rare, life-threatening hematologic disease characterized by thrombocytopenia, hemolytic anemia, and small clots forming in the smallest arteries that cause disturbances in the nervous system and other organs. Although the exact cause of TTP is unknown, this disease is thought to be generally associated with a deficiency in the ADAMTS13 enzyme, which is responsible for breaking down clotting protein von Willebrand factor. TPP can either be inherited, known as congenital TTP (cTTP, Upshaw-Schulman Syndrome), or acquired, known as immune-mediated TTP (aTTP or iTTP). Deficiency of ADAMTS13 appears to be caused by mutations of the ADAMTS13 gene in cTTP and by ADAMTS13 autoantibodies in aTTP.

aTTP typically presents as fatigue, dyspnea, petechiae, or other bleeding due to severe microangiopathic hemolytic anemia (MAHA) and thrombocytopenia in a previously healthy individual, although it may also present in patients with other autoimmune disorders, such as systemic lupus erythematosus (SLE). Not all patients' symptoms manifest as critical illness, with some presenting with minor complaints involving the nervous system (weakness/dizziness), gastrointestinal system (abdominal pain/nausea/vomiting), or easy bruising.

Plasma exchange is the standard of care for aTTP and prevents progression to neurologic deterioration, cardiac ischemia, irreversible renal failure, and death if left untreated. Prior to the widespread use of plasma exchange, the condition was associated with a 90% mortality rate, but with the treatment, an estimated 80% of patients recover. Glucocorticoids and rituximab further improve outcomes of plasma exchange and are generally administered concurrently and continued after discontinuation of plasma exchange.

In 2019, Sanofi's Cablivi was approved for the treatment of adult patients with aTTP, in combination with plasma exchange and immunosuppressive therapy. The efficacy of Cablivi to treat pediatric patients with aTTP was evaluated in a retrospective chart review study of 30 patients ranging in age from 2-18 years old. Results showed that 80% of patients achieved clinical remission, defined as achieving a normal platelet count and having LDH levels (a marker of red blood cell breakdown) less than 1.5 times the upper limit of normal for 30 days or more. In 2025, its label was expanded to include children 12 years of age and older.

Summary

Effective Date of Policy:	2/12/2026
Indications	Treatment of adult and pediatric patients 12 years of age and older with acquired thrombotic thrombocytopenic purpura (aTTP), in combination with plasma exchange and immunosuppressive therapy
ICD10 Diagnosis Codes	M31.1
HCPCS	C9047
Availability	11 mg single-dose vial of lyophilized powder
Duration	Initial: 1 month Continuation: up to 30 days

Required Criteria for Initial Approval

All of the following conditions for the requested indication must be met in order to approve therapy

1. The medication must be prescribed by, or in consultation with, a hematologist AND
2. The patient must be at least 12 years of age or older AND
3. Must have a diagnosis or suspected diagnosis of acquired thrombotic thrombocytopenic purpura (aTTP) AND
4. Must be used in combination with plasma exchange and immunosuppressive therapy (such as systemic corticosteroids or a rituximab-containing product)
5. If the above criteria are met, Cablivi will be approved for 1 month under the medical benefit for administration while the patient is receiving plasma exchange.

Continuation Criteria

Continued coverage post-plasma exchange, under the pharmacy benefit, will require the following:

- Documentation confirming a diagnosis of aTTP (i.e., suppressed ADAMTS13 activity levels, etc.) AND
- Documentation confirming the patient has not had more than 2 recurrences of aTTP while on therapy with Cablivi (a recurrence is defined as thrombocytopenia occurring after initial recovery of platelet count that requires re-initiation of daily plasma exchange) AND
- The date of last plasma exchange treatment AND
- The number of remaining doses (dosed once daily) needed to complete the post-plasma exchange treatment phase (maximum 30 days of treatment post-plasma exchange is allowed for the initial treatment course)
- Cablivi will be approved under the pharmacy benefit in accordance with the number of remaining doses required to complete the initial treatment course (up to 30 days postplasma exchange). For example, for a patient needing 24 doses to complete the initial treatment course will be approved for 24 days of treatment

Requests for additional therapy (after 30 days of treatment post-plasma exchange) will be approved for a maximum of 28 additional days if the provider submits the following:

- Documentation of remaining signs of persistent underlying disease (such as suppressed ADAMTS13 activity levels) AND
- Documentation confirming the patient has not had more than 2 recurrences of aTTP while on therapy with Cablivi (a recurrence is defined as thrombocytopenia occurring after initial recovery of platelet count that requires re-initiation of daily plasma exchange)

Considerations

- Cablivi should be discontinued if the patient experiences more than 2 recurrences of aTTP while on Cablivi
- Patient must have medical drug coverage administered by CDPHP for the initial dosing period during plasma exchange
- Patient must have pharmacy drug coverage administered by CDPHP for subsequent dosing after the plasma exchange period
- Prior authorization is obtained through the CDPHP pharmacy department.

MEDICAL POLICY

Medical Policy Title	**Capsule Endoscopy**
Policy Number	**6.01.27**
Current Effective Date	**November 1, 2026**
Next Review Date	**October 2027**

Our medical policies are based on the assessment of evidence based, peer-reviewed literature, and professional guidelines. Eligibility for reimbursement is based upon the benefits set forth in the member's subscriber contract. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Capsule endoscopy (CPT 91110, 91111) is considered **medically necessary** for **ANY** of the following indications:

A. To investigate suspected small bowel bleeding when conventional diagnostic workup failed to identify the source of bleeding (e.g., persistent or recurrent iron-deficiency anemia, positive fecal occult blood test, or visible bleeding);

B. For the initial diagnosis of suspected Crohn's disease (CD) when conventional diagnostic work-up failed to reveal evidence of disease, and there remains a strong clinical suspicion of CD (e.g., chronic diarrhea, abdominal pain, weight loss, fatigue, fever, anemia, elevated white blood cell (WBC) count, or elevated laboratory markers of inflammation);

C. For re-evaluation of members with an established diagnosis of Crohn's disease who remain symptomatic despite appropriate medical therapy;

D. Surveillance of the small bowel in members with a diagnosis of hereditary polyposis syndromes (i.e., familial adenomatosis polyposis [FAP] or Peutz-Jeghers syndrome);

E. For re-evaluation of members with an established diagnosis of celiac disease who remain symptomatic despite adherence to appropriate medical therapy;

F. Screening or surveillance of esophageal varices, in cirrhotic patients with significantly compromised liver function (e.g., Child-Pugh score of Class B or greater), where a standard upper endoscopy with sedation or anesthesia is contraindicated.

II. Capsule endoscopy is considered **investigational** for the evaluation or diagnosis of **ANY** other indication, including but not limited to:

A. Disease of the esophagus, other than as stated above;

B. Disease in the small bowel, other than as stated above;

C. Confirmation of lesions/pathology found by other diagnostic means;

D. Other GI diseases/conditions not presenting with GI bleeding (e.g., irritable bowel syndrome, portal hypertensive enteropathy, unexplained chronic abdominal pain);

E. Disease of the stomach (e.g., NaviCam, CPT 0651T);

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

F. Disease of the large intestine/colon (e.g., detection of colonic polyps or colon cancer) (e.g., PillCam COLON2).

G. GI motility disorder (e.g., gastroparesis) (e.g., MotiliCap, Atmo Gas Capsule CPT 91112);

H. GI stricture(s) or obstruction (e.g., Pillcam Patency Capsule, CPT 91299);

I. Disease evaluation by magnetic capsule endoscopy (e.g., NaviCam, CPT 0651T);

J. Detection of GI blood (Pill Sense System, CPT 0977T).

POLICY GUIDELINE(S)

I. Capsule endoscopy (CE) must be performed under the supervision of a gastroenterologist with expertise in this technology and performed only when there is no suspected or confirmed gastrointestinal (GI) obstruction.

II. In the case of suspected small bowel bleeding, because of low lesion detection rate, a small bowel follow-through or enteroclysis is not necessarily required prior to CE. A small bowel follow-through may be beneficial in some cases, at the discretion of the clinician, prior to or after CE, in the detection of small bowel lesions and in their anatomical localization.

DESCRIPTION

Capsule endoscopy (CE), also known as wireless capsule endoscopy (WCE) or video capsule endoscopy, is a non-invasive diagnostic imaging device used to visualize segments of the esophagus, stomach, small bowel, and colon. The CE capsule is swallowed by the patient, propelled by peristalsis or magnetically-controlled through the gastrointestinal tract, and either dissolves (e.g., patency capsule) or is naturally excreted. As the capsule is propelled through the gastrointestinal (GI) tract, the capsule records and transmits data (e.g., images or electrical signals) for interpretation.

Small Bowel Capsule Endoscopy

The primary indications for capsule endoscopy including identifying the source of suspected small bowel bleeding when conventional diagnostic work-up failed to provide a definitive diagnosis; for the initial diagnosis of suspected Crohn's disease when conventional diagnostic work-up failed to provide a definitive diagnosis, to evaluate refractory celiac disease; and screen/surveillance of tumors in the small bowel in people diagnosed with polyposis genetic syndromes.

Colon Capsule Endoscopy (CCE)

Screening for colon cancer is suboptimal in the United States. To improve acceptability of screening, the colon capsule (PillCam Colon Capsule, Given Imaging) was developed as a non-invasive technique to explore the colon without intubation, sedation, and air insufflation. Bowel preparation is crucial

with CCE since it is not possible to clean the colon during the procedure and even the smallest amount of debris could interfere with identifying colonic polyps.

CCE is being investigated as a screening tool for colorectal polyps, including for individuals with an incomplete colonoscopy despite adequate bowel preparation. In such cases, full visualization of the colon is not technically achievable, limiting the ability to detect polyps and guide subsequent clinical decisions. Contributing factors to an incomplete colonoscopy include patient discomfort, diverticulosis, tortuosity, adhesions due to prior surgeries, angulation or fixation of bowel loops, ineffective sedation, and endoscopist and technician expertise.

Blood Detection Capsule

A novel device intended to be used for the detection of blood GI tract, the capsule features sensors that detect blood and wirelessly transmit data to an external receiver. The capsule makes its way through the gastrointestinal tract and is then passed naturally from the body. The reusable receiver collects and displays real-time information gathered by the capsule. The receiver interprets the data and displays a sensor output value. It plots these values on a chart using data acquisition and when completed displays a "blood detected" or "no blood detected" message. The software supports entering of the patient information, pairing of the receiver and capsule and data interpretation and display.

Esophageal Capsule

Capsule endoscopy is proposed as an option to visualize and detect mucosal disease of the esophagus (e.g., esophageal varices) and could triage patients for endoscopy if either the sensitivity or the specificity is high. Traditional endoscopy could then be performed on the appropriate group to determine false-positives or false-negatives, having spared the group with a high positive predictive value an endoscopy procedure.

A novel diagnostic ingestible capsule sponge device, the Cytosponge Cell Collection Device, is being investigated as a diagnostic tool for a wide range of upper GI conditions. The endoscopic cell collection device consists of a compressed spherical sponge inside a capsule, which is attached to a suture. The capsule is swallowed and dissolves in the stomach releasing the self-expanding sponge that collects cells from the outer layer of the esophageal tissue. The sponge is removed using the attached suture and the esophageal surface cells undergo cytological and histological analysis.

Magnetically Controlled Capsule Endoscopy

Magnetically controlled capsule endoscopy, also referred to as magnetically assisted capsule endoscopy (MACE), is being investigated for visualization of the stomach and duodenum to evaluate unexplained abdominal pain. The indication for use includes adults (≥22 years old) with a BMI less than 38. The system can be used in clinics and hospitals, including ER settings. This non-invasive system consists of a single-use ingestible capsule and magnet linked to a physician-operated console. The capsule contains a camera that wirelessly captures images of the desired anatomy. The console allows the operator to control the motion and direction of the capsule, ensuring visualization of the entire stomach. The capsule's camera captures images and transmits the images to a data recorder for interpretation. The procedure does not require sedation and has a procedural time of

approximately 15 to 20 minutes. The capsule leaves the body in 24 hours on average but may take as long as two (2) weeks. The device is contraindicated for use in patients with gastrointestinal obstruction, stenosis, fistula, or those with dysphagia. Other contraindications include patients with cardiac pacemakers or other implantable electronic medical devices as well as pregnant women, those less than 22 years of age, and those with a body mass index of 38 or greater.

Motility Capsule

The motility capsule is an alternative to gastric scintigraphy, which is considered the reference standard for diagnosing gastroparesis. The American Gastroenterological Association (AGA) defines gastroparesis as delayed gastric emptying of the stomach, possibly due to issues with the stomach muscles, nerves, or brain and spinal cord nerves. Gastroparesis is not a mechanical block in the stomach. Symptoms of gastroparesis are often nonspecific and may mimic other gastrointestinal tract disorders. Gastroparesis can be caused by many conditions, with most common causes including idiopathic, diabetic, or postsurgical. During wireless GI motility monitoring, the individual swallows a small capsule that contains sensors to measure gastrointestinal transit times and assess GI motility disorders.

Patency Capsule

The patency capsule (e.g., Pillcam Patency Capsule) is a dissolvable capsule developed to verify adequate patency of the gastrointestinal tract prior to administration of the wireless CE in patients with known or suspected strictures. Once the patient ingests the patency capsule, it is propelled through the GI tract by normal peristalsis. If the patency capsule is excreted structurally whole, then this indicates patency of the patient's GI tract, and a PillCam capsule can be administered.

SUPPORTIVE LITERATURE

Small Bowel Capsule Endoscopy

Suspected Small Bowel Bleeding

For individuals who have suspected small bowel bleeding (previously referred to as obscure gastrointestinal [GI] bleeding) who receive wireless capsule endoscopy (CE), the evidence includes numerous case series and a randomized controlled trial (RCT). The evidence has demonstrated that CE can identify a bleeding source in a substantial number of patients who cannot be diagnosed by other methods, with a low incidence of adverse events. Because there are few other options for diagnosing obscure small bowel bleeding in patients with negative upper and lower endoscopy, this technique likely improves health outcomes by directing specific treatment when a bleeding source is identified. The evidence is sufficient to determine that the technology results in an improvement in the net health outcome.

A small randomized controlled trial (RCT) compared CE with mesenteric angiography in patients with acute melena or hematochezia (Leung 2012). While CE had a higher diagnostic yield (DY), secondary outcomes such as transfusion, hospitalization, and mortality did not differ significantly between groups. A large number of uncontrolled studies have evaluated the use of CE in the evaluation of patients with suspected small bowel bleeding. These studies have consistently reported that a

substantial proportion of patients receive a definitive diagnosis following this test when there are few other diagnostic options.

A meta-analysis of 24 studies estimated that the DY in this patient population was approximately half of the included patients and was higher in patients with documented iron-deficiency anemia (Koulaouzidis 2012). Capsule endoscopy appears to locate the source of bleeding at least as well as other diagnostic methods and direct treatment to the source of bleeding.

Crohn's Disease (CD)

The evidence is sufficient to determine that CE for suspected and established diagnosis of CD results in an improvement in the net health outcome.

The Selecting Therapeutic Targets in Inflammatory Bowel Disease (STRIDE) initiative began in 2015, with an updated STRIDE-II published by Turner et al (2021). STRIDE-II encompasses evidence- and consensus-based recommendations for treat-to-target strategies in adults and children with inflammatory bowel disease (IBD). Consensus recommends endoscopic and transmural assessment of healing by sigmoidoscopy or colonoscopy; however, when not feasible, alternatives can include CE. The authors acknowledge that transmural healing in Crohn's disease is becoming an important adjuvant assessment of the depth of treatment response; however, more research is needed to determine the incremental gain derived from the goal and whether the gain is worth the therapy-related risks and costs.

Choi et al (2017) conducted a meta-analysis comparing CE with various modalities for diagnosing CD. The analysis consisted of 24 trials (RCT, nonrandomized, and diagnostic accuracy studies) with suspected or established CD. In the pooled analysis, in patients with suspected CD, the sensitivity of CE ranged from 89.6% to 92.0% and the specificity was 100%.

Kopylov et al (2017) published a systematic review of studies evaluating the use of CE for CD. Reviewers included prospective studies comparing CE with magnetic resonance enterography (MRE) and/or small bowel (SB) contrast ultrasound in patients who had suspected or established CD. In the pooled analyses of the 11 studies that included patients with established CD, the diagnostic yield of CE for detection of active small bowel CD was similar to that of MRE and to ultrasound. The outcomes were similar for the subgroups of suspected versus established CD and adult versus pediatric patients. CE was superior to MRE for proximal SB CD. The summary of results demonstrate that all have similar DY for the detection of SB CD; none of the modalities can be considered superior over the others and their utilization should be tailored to the specific clinical situations. CE is the preferred modality for detection of proximal small bowel involvement.

Bruining et al (2020) reported results from the multicenter, prospective BLINK trial comparing the diagnostic accuracy of CE compared to ileocolonoscopy (IC) and/or MRE in patients with established CD. The per-protocol analysis included 99/158 enrolled subjects with 16 patients tested by all 3 modalities. The reference standard was defined as the presence or absence of inflammation as designated by the modality-specific scoring system at prospective interpretation by expert central readers. Overall sensitivity for active enteric inflammation (CE vs MRE and/or IC) was 94% vs 100% (p=0.125) and specificity was 74% vs 22% (p=0.001). Sensitivity of CE was superior to MRE for

enteric inflammation in the proximal small bowel (97% vs 71%, p=0.021), and similar to MRE and/or IC in the terminal ileum and colon (p=0.500-0.625). There were seven serious adverse advents of which three were related to the CE device. Several limitations to this study are noted. The authors concluded that this study demonstrates the powerful potential of panenteric CE to provide accurate Crohn's disease assessments and panenteric CE should be considered for utilization in non-structuring Crohn's disease evaluations.

Elosua et al (2022) evaluated the therapeutic impact of CE in patients with established CD in a retrospective, single-center study. Therapeutic impact was defined as change in CD-related treatment recommended based on CE results. A total of 305 patients with established CD underwent a small bowel capsule endoscopy (SBCE) between January 2008 and December 2019. From the 432 procedures performed, 87.5% were conclusive. Active disease was present in 63 patients; 41.6% mild inflammation and 21.9% moderate-to-severe activity. Disease activity demonstrated by CE results was correlated with therapeutic changes. A change of management was guided by SBCE in 51.3% of procedures. Mucosal healing assessed via CE was the only independent factor that predicted therapy de-escalation. Study limitations include the retrospective study design and limited heterogeneity due a limited group of research gastroenterologists.

Celiac Disease

For a suspected diagnosis of celiac disease, the clinical validity of wireless CE for diagnosing celiac disease has not been established and its diagnostic performance is currently insufficient to replace standard modalities or to effectively triage patients to other diagnostic approaches. The evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

A meta-analysis by El-Matary et al (2009) compared the diagnostic performance of CE with a reference standard of duodenal biopsy. The pooled analysis of 3 studies showed a sensitivity of 83% and a specificity of 98%. Rokkas and Niv (2012) conducted a meta-analysis to compare the diagnostic performance of CE with biopsy, summarizing 6 studies (N=166 subjects). The overall pooled sensitivity was 89%, and the specificity was 95%. Capsule endoscopy detected involvement of intestines beyond the duodenum; however, the clinical significance of detecting the extent of celiac disease is uncertain. Given the less than 90% sensitivity of CE for celiac disease, it does not appear to be an adequate alternative method of making an initial diagnosis.

Kurien et al (2013) conducted a non-randomized study of 62 patients with an equivocal diagnosis of celiac disease and 69 patients with confirmed celiac disease who were unresponsive to standard treatment were evaluated with CE. Results were combined with human leukocyte antigen typing and response to gluten challenge, with the final diagnosis made by three expert physicians who received the information from all three sources. The main outcome was the increase in diagnostic yield after CE combined with the other tests. The diagnostic yield was greatest in cases with antibody-negative villous atrophy where a diagnosis of celiac disease was made in 9 of 32 patients (28%). In eight of the 69 nonresponsive celiac disease patients (12%), CE identified 2 cases of enteropathy-associated lymphoma, 4 type 1 refractory disease cases, 1 fibroepithelial polyp, and 1 case of ulcerative jejunitis. This study was limited by the small sample size and use of other tests in conjunction with CE to ascertain a final diagnosis.

Shapiro and Niv (2025) conducted a systematic review and meta-analysis to assess the diagnostic yield of video capsule endoscopy (VCE) in patients with CD. Analyzing data from 22 studies involving 1,585 patients, the authors found that VCE identified pathognomonic features of CD (e.g., villous atrophy, scalloping, mosaic patterns, fissuring, ulcers, and erosions) in approximately 60% of cases. The pooled effect size for any diagnostic pathology was 0.601, with higher yields observed in patients with refractory CD. VCE achieved complete small bowel visualization in over 96% of patients, which the authors concluded demonstrate its utility as a non-invasive, high-resolution imaging modality for evaluating mucosal abnormalities, especially when conventional endoscopy is inconclusive or incomplete. Study limitations include small sample sizes, unblinded studies, and high heterogeneity across studies. The authors concluded that their findings suggest that VCE offers a moderate diagnostic yield for celiac disease, with a possible role in early management and diagnosis of refractory celiac disease (RCD). Future studies should aim to standardize protocols and explore the effectiveness of VCE using artificial intelligence and machine learning to complement existing diagnostic methods.

Inherited Polyposis Syndromes

Small bowel capsule endoscopy (SBCE) can be used as a surveillance tool for small bowel polyps in patients with inherited polyposis syndromes. SBCE has been found to have a better diagnostic capability to reveal small bowel polyps, compared to barium follow-through, in patients with Peutz-Jeghers syndrome (Brown 2006; Iaquinto 2008; Urquhard 2014).

Lynch Syndrome

At present, the evidence is insufficient to determine that the technology results in an improvement in the net health outcome and surveillance of the small bowel is not generally recommended as a routine intervention for patients with Lynch syndrome.

Saurin et al (2010) conducted a small prospective, blinded, comparative study of CE and computed tomography (CT) enteroclysis with 35 asymptomatic patients with Lynch syndrome. Small bowel neoplasms were diagnosed in three patients (8.6%). Capsule endoscopy identified all neoplasms, and CT enteroclysis raised suspicion of one neoplasm (adenocarcinoma) but missed the two others. The clinical usefulness of systematic small-bowel screening in these patients should be confirmed through large prospective studies.

Haanstra et al (2015) evaluated 200 patients with Lynch syndrome who underwent video CE to determine the prevalence of small-bowel neoplasia in asymptomatic patients with Lynch syndrome. Small bowel neoplasia was detected in the duodenum in two patients (1 adenocarcinoma, 1 adenoma). In another patient, a duodenal cancer was diagnosed 7 months after a negative video CE, which is considered a lesion missed by CE. All three neoplastic lesions were within reach of a conventional gastroduodenoscope.

Valdivia et al (2024) report that the role of small bowel (SB) cancer surveillance by CE in Lynch syndrome patients has been investigated, with contradicting results. The authors conducted a systematic review and meta-analysis to evaluate the diagnostic yield (DY) of CE as a screening tool in asymptomatic LS patients. Five studies, comprising 428 patients and 677 CE procedures, were

included for data extraction and statistical analysis. The estimated pooled DY for CE-identified pathological findings was 8% in the first screening round and 6% in the second. Limiting the analysis to histologically confirmed pathological findings, the pooled DY of second-round screening dropped to 0%. The included studies showed a significantly different prevalence of pathogenic variants in mismatch repair (path_MMR) genes, which underlie different cumulative incidences of extracolonic cancers. SB surveillance by CE with a 2-year interval in asymptomatic LS individuals does not appear to be an effective screening strategy. Confirmatory prospective studies in this context are needed, considering the different cumulative incidence of SB tumors according to underlying path_MMR defects. The authors concluded that, although the DY of CE is high in detecting small bowel lesions in LS, the low number of positive examinations eventually resulted in an even lower number of true-positive patients after histological confirmation, with a pooled yield proximate to 0%. SB surveillance by CE with a 2-year interval in asymptomatic LS individuals does not appear to be an effective screening strategy.

Blood Detection Capsule Endoscopy

Akiki et al (2024) reported findings from a prospective, open-label, single-arm comparative clinical trial to evaluate the safety and efficacy of the PillSense System, a novel ingestible capsule designed to rapidly detect upper gastrointestinal bleeding (UGIB). Physicians conducting the esophagogastroduodenoscopy (EGD) were blinded to the PillSense results. The study involved 126 adults with suspected UGIB who received the capsule followed by EGD within four hours. Compared with EGD results, the capsule correctly detected the presence of blood in 26 of 28 cases and the absence of blood in 87 of 96 cases. Sensitivity and specificity were 92.9% (P = .02) and 90.6% (P < .001), respectively. Among the 126 patients in the safety population, 23 (18.3%) experienced at least 1 AE. This industry sponsored study concluded that the novel blood-sensing capsule device provides highly accurate and rapid detection of UGIB. However, future studies are needed to identify and validate the performance of the PillSense system in a real-world clinical setting.

Colon Capsule Endoscopy

Colon capsule endoscopy (CCE) has been proposed as an alternative imaging modality to explore mucosa of the entire colon. CCE does not allow for biopsy or polyp removal; therefore, patients with lesions detected typically require subsequent colonoscopy for further evaluation and/or treatment. Studies looking at the efficacy of colon capsule endoscopy compared with standard colonoscopy have reached variable results. Most studies report sensitivities for detecting polyps ≥ 6 mm between 70 and 88 percent (range 39 to 88 percent), and specificities between 80 and 90 percent (range 64 to 93 percent) (Cave et al., 2024). The evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

Given Imaging conducted an 884-patient, 16-site clinical trial that studied the accuracy and safety of PillCam COLON 2, compared to optical colonoscopy, in detecting adenomas 6 millimeters or larger. Results from this clinical trial demonstrated that the sensitivity for PillCam COLON was 88% and specificity was 82% in detecting adenomas at least 6 mm in size. The FDA based its clearance decision on an analysis of this clinical trial data, which used a more restrictive methodology for matching polyps. In this analysis, which was conducted on hyperplastic polyps and adenomas, the

positive percent agreement for PillCam COLON and optical colonoscopy was 69%, and negative percent agreement was 81% for polyps at least 6 millimeters in size. The wireless capsule had not been adequately studied in the large intestine. The colon was not well-visualized due to stool obscuring the colonic mucosa. Adequate visualization of the colon was also hampered by the colon's larger diameter which made it possible for the capsule camera to miss suspicious areas.

Eliakim et al (2006) conducted a prospective study to determine whether CE of the colon can provide similar detection rates of pathological colonic conditions, compared to conventional colonoscopy. Conventional colonoscopy detected more polyps compared to wireless CE: 70% were identified with the capsule and 16/20 (80%) were identified by conventional colonoscopy. In comparison with conventional colonoscopy, false-positive findings on PillCam Colon capsule examination were recorded in 15/45 cases (33%). Additional studies are needed, to evaluate the accuracy of PillCam Colon endoscopy in patient populations with different prevalence levels of colonic disease.

Parodi et al (2018) stated that CCE has been recognized as an alternative for colorectal cancer (CRC) screening in average-risk people; however, in first-degree relatives (FDRs) of patients with inherited predispositions to CRC have a much higher increased risk of developing CRC but compliance with colonoscopy screening by FDRs remains suboptimal. The researchers conducted a prospective study to assess the accuracy of CCE as a screening tool in FDRs of people with CRC. An optical colonoscopy (OC) with segmental unblinding was the reference standard. In this study, 177 FDRs underwent both CCE and optical colonoscopy (OC), with segmental unblinding of CCE findings used to validate results. CCE demonstrated a sensitivity of 91% for detecting polyps ≥ 6 mm, identifying 51 of 56 cases, and a specificity of 88%, correctly classifying 107 of 121 participants without lesions of this size. The positive predictive value (PPV) and negative predictive value (NPV) for polyps ≥ 6 mm were 78% and 95%, respectively. For polyps ≥ 10 mm, CCE achieved a sensitivity of 89% (24 of 27 cases) and a specificity of 95% (142 of 150 cases). Limitations to the present analysis include the study design and lack of analysis of FDRs' compliance with CCE screening. The authors concluded that the results showed both high technical feasibility and accuracy of CCE as a primary screening test for FDRs of patients with CRC, supporting its use for such an indication.

Kjolhede et al (2020) reported a systematic review and meta-analysis of the diagnostic accuracy of CE compared to colonoscopy with stratified results for polyps of any size, polyps ≥ 6 mm, and polyps ≥ 10 mm. Across analyzed patients in the 12 eligible studies, the indications for endoscopy included colorectal cancer screening or history of polyps or colorectal cancer (n=1200; 63.2%), positive fecal immunochemical test (n=493; 26%), first-degree relatives of patients with colorectal cancer (n=177; 9.3%), or unspecified (n=28; 1.5%). The rate of patients with an adequate bowel preparation ranged from 40% to 100%. The rates of complete CE transits ranged from 57% to 100%. The authors note that the relatively high rate of incomplete CE investigations limits the utility of CE in the colorectal cancer setting. All but one study was assessed to have a high risk of bias and applicability concerns for the reference standard.

Cash et al (2021) evaluated the diagnostic characteristics of CE using subsequently performed colonoscopy as the reference standard. Randomizing patients to colon CE or computed tomography (CT) colonography followed by optical colonoscopy. Data from 286 patients revealed that the proportion of enrollees with any polyp 6 mm or larger confirmed by subsequent blinded optical

colonoscopy was 31.6% for colon CE versus 8.6% for CT colonography. The sensitivity and specificity of colon CE for polyps 6 mm or larger was 79.2% and 96.3%, respectively, while that of CT colonography was 26.8% and 98.9%. For polyps 10 mm or larger, the sensitivity and specificity of colon CE was 85.7% and 98.2% compared with 50% and 99.1% for CT colonography. The authors concluded that colon CE should be considered comparable or superior to CT colonography as a screening test; however, neither test was as effective as optical colonoscopy.

Lei et al (2025) conducted a systematic review and meta-analysis evaluating follow-up endoscopy rates (FERs) as a measure of effectiveness in colon capsule endoscopy (CCE). Analyzing data from 19 studies involving 2,850 patients, the study found that 42% of individuals undergoing CCE required a follow-up endoscopic or radiologic investigation, which is significantly higher than FERs for colonoscopy (10–15%) and CT colonography (25%). Reinvestigation was more frequent with the newer CCE2 capsules, likely due to improved diagnostic performance Despite applying meta-regression and subgroup analyses, substantial heterogeneity was observed across study results, largely attributable to multiple confounding variables. The authors concluded that further research is needed to reduce CCE FERs, which is essential for improving patient outcomes and ensuring CCE becomes a viable and widely adopted service in clinical practice.

Colon Capsule Endoscopy (CCE) Following Incomplete Optical Colonoscopy

Hussey et al. (2018) state that CCE is a new, noninvasive technique for exploring the large intestine, with recent studies demonstrating good correlation between OC and CCE in detecting both significant and non-significant large bowel pathology. The researchers conducted an observational, prospective, single-center study to assess the efficacy of same-day CCE following incomplete OC in an unselected patient cohort. Patients (n=50) with an incomplete OC for reasons other than obstruction or inadequate bowel preparation were recruited. CCE was performed using the second-generation PillCam colon capsule (Medtronic/Given Imaging, Yokneam, Israel) after a minimum one-hour recovery period following OC. Although only 76% (n=38) of CCEs were complete, full colonic views were obtained in 84% (n=42) of cases. OC findings prior to CCE were normal in 76% (n=38), diverticular disease in 24% (n=12) and polyps which were removed in 12% (n=6). CCE findings were normal in 26% (n=13), polyps 38% (n=19), inflammation 22% (n=11), diverticular disease 25% (n=12), angiodysplasia 3% (n=1), and cancer 3% (n=1). Among patients with polyps (n=19), seven (36%) were deemed to have significant polyps requiring referral for polypectomy. Of these, four patients had a polyp > 6 mm and three patients had ≥ 3 polyps. Subsequent histology of the referred polyps (n=14) revealed tubulovillous adenoma with low-grade dysplasia in 57% of cases (n=8), tubulovillous adenoma with high-grade dysplasia in 7% (n=1), sessile-serrated adenoma in 14% (n=2) and hyperplastic polyps in 21% (n=3). Significant small bowel findings were identified in three cases, including Crohn's disease and a neuroendocrine tumor. A major adverse event occurred in one patient due to capsule retention which required surgical resection. The authors acknowledged several study limitations; however, they concluded that same-day CCE following incomplete OC is a safe and feasible alternative for assessing unexplored segments of the colon in selected patients.

Baltes et al (2018) conducted a prospective multicenter observational study in Germany to evaluate the ability of PillCamColon2 to visualize colonic segments missed during incomplete optical colonoscopy (OC) and to assess the DY. Data from 74 patients were analyzed (51% in group A; 49%

in group B). Reasons for referral to colonoscopy were CRC screening (22%), anemia (15%), hematochezia (15%), irregular stool (12%), abdominal pain (12%), B symptoms (7%), colitis (5%) and other reasons (12%). Bowel cleansing was adequate in 67% of cases, and CCE could visualize colonic segments missed by incomplete colonoscopy in 90% of patients under protocol A and 97% of patients under protocol B (p = 0.35). Significant polyps, including adenocarcinoma, were detected in 24% of cases. Detection rates for all polyps and significant polyps per patient were similar in both protocols. Polyps were found predominantly in the right colon (86%) in segments that were not reached by optical colonoscopy. Extracolonic findings (e.g., reflux esophagitis, suspected Barrett esophagus, upper GI-bleeding, gastric polyps, gastric erosions) were identified in eight patients. PillCamColon2 capsule was retained in the ileum of one patient without symptoms. The authors report that the second-generation CCE using low-volume bowel preparations is useful, well tolerated, and capable of detecting additional relevant lesions. Although the risk of capsule retention is low, comparable to that of small bowel capsule endoscopy, it must still be considered. Future studies should focus on improving colon cleansing and the completeness of CCE following incomplete OC.

Esophageal Capsule

Capsule endoscopy has been used to diagnose portal hypertensive enteropathy (PHE) particularly in patients with portal hypertension and suspected small-bowel bleeding or anemia. Based on the outcomes of small studies comparing the Pill Cam ESO to upper endoscopy in patients with portal hypertension and esophageal varices, the PillCam ESO represents an accurate, non-invasive alternative to EGD for the detection of esophageal varices and portal hypertensive gastropathy (Eisen 2006; Lapalus 2006; Penna 2008; Lu 2009). While further studies are required to validate these initial findings, the use of wireless CE for those patients with significantly compromised liver function, who cannot tolerate sedation or anesthesia, appears reasonable.

Barrett Esophagus

Capsule endoscopy is being investigated as a diagnostic screening technique for esophageal conditions (e.g., Barrett esophagus); however, the clinical validity of wireless CE for monitoring esophageal disorders has not been established. Other available modalities are superior to CE for monitoring esophageal disorders. The diagnostic characteristics of CE are inadequate to substitute for other modalities or to triage patients to other modalities.

The Cytosponge cell collection device (Medtronic), an ingestible capsule containing a 'sponge on a string,' is being investigated as a minimally invasive method of sampling surface esophageal cells in patients who require screening or surveillance of esophageal pathologies such as Barrett's Esophagus (BE). However, current evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

Eliakim et al (2004) conducted a feasibility case series study to compare the PillCam ESO to conventional upper endoscopy in patients with suspected disorders of the esophagus (n= 17 patients). The negative predictive value for any esophageal disorder was 100%, while the positive predictive value was 92% (sensitivity 100%, specificity 80%). The authors stated that further, large-scale studies are necessary to fully assess this diagnostic tool.

Eliakim et al (2005) conducted a larger, multi-center study of 106 patients with either GERD or Barrett's esophagus. The authors reported esophageal abnormalities in 66/106 patients, providing a sensitivity of 92% and specificity of 95%.

Lin et al (2007) conducted a prospective, multi-center, blinded study to evaluate the accuracy of esophageal capsule endoscopy (ECE) in diagnosing Barrett's esophagus. Of the 96 subjects enrolled, 90 (94%) completed the study, including 66 screening and 24 surveillance patients. ECE demonstrated a sensitivity of 67% and a specificity of 84% for identifying Barrett's esophagus, correctly diagnosing 14 of 21 biopsy-confirmed cases. Among screening patients, the positive predictive value was 22%, and the negative predictive value was 98%. Sensitivity was similar for both short- and long-segment Barrett's esophagus. The authors concluded that ECE has only moderate sensitivity and specificity for detecting Barrett's esophagus, and while not suitable as a primary screening tool in its current form, ECE may be considered for patients unwilling to undergo esophagogastroduodenoscopy (EGD).

Iqbal et al (2018) conducted a systematic review to analyze the efficacy and safety of a minimally invasive cell sampling device (Cytosponge) in the diagnosis of esophageal pathology. A total of 13 studies were include in the review, with six studies observing the efficacy of the Cytosponge in diagnosis Barrett's esophagus (BE) undergoing EGD and three in diagnosing eosinophilic esophagitis (EoE). The pooled sensitivity and specificity of diagnosing BE through the sponge devices were 81 and 91%, respectively. The pooled sensitivity and specificity of detecting EoE was calculated at 76.3% and 98.8%, respectively. Although published studies have good quality and showed promising results, the major limitation is that the majority were performed by a single group of authors. The authors concluded that given the current favorable results, the product should be independently verified to avoid the potential biases and conflicts inherent to the current literature.

Xu et al (2019) conducted a pilot study, SUGAR, to explore the feasibility of combining serological testing with Cytosponge technology to screen for upper gastrointestinal adenocarcinoma risk. Blood samples from 56 patients with Barrett's esophagus and 202 non-Barrett controls who previously took part in a trial assessing the accuracy of the Cytosponge for Barrett's esophagus were assessed for serum pepsinogen (PG) 1 and 2, gastrin-17, trefoil factor 3 (TFF3) and Helicobacter pylori infection.

The researchers found that low serum PG1 levels were significantly associated with gastric symptoms but not with Barrett's esophagus, suggesting its potential utility in identifying patients at risk for gastric pathology. Patients without a diagnosis of Barrett's esophagus had significantly lower serum values for PG1 levels (100.7 vs 292.0 ng/mL), PG2 (6.0 vs 13.9 ng/mL) and G17 (4.8 vs 13.4 ng/mL) than those with Barrett's metaplasia ($p<0.001$). Patients with Barrett's esophagus did not show pathologically altered serum PGs. Although serum trefoil factor 3 (TFF3) has been reported as a stable marker for gastric atrophy, assessment of TFF3 did not add further value to that of PG1. Prospective validation is needed to assess if the combination of a serum markers for gastric pathology with the minimally invasive Cytosponge test for Barrett's esophagus could be a potentially complimentary strategy to identify patients at risk for upper gastrointestinal adenocarcinoma.

Fitzgerald et al (2020) conducted the Barrett's Esophagus Screening Trial 3 (BEST3) study to investigate whether offering the Cytosponge-trefoil factor 3 (TFF3) to patients on medication for

gastro-esophageal reflux would increase the detection of Barrett's esophagus compared with standard management. This multicenter, pragmatic, RTC was real-world implementation of the Cytosponge-TFF3, conducted in 109 socio-demographically diverse general practice clinics in England. Randomization occurred at both the general practice clinic level (cluster randomization) and at the individual patient level, and the results for each type of randomization were analyzed separately before being combined. Participants received either standard management for gastroesophageal reflux (usual care group), in which endoscopy was performed only if deemed necessary by the general practitioner, or usual care plus an offer of the Cytosponge–TFF3 procedure, followed by endoscopy if TFF3-positive cells were identified (intervention group). The primary outcome was the diagnosis of Barrett's esophagus at 12 months after enrollment, expressed as a rate per 1000 person-years, in all participants in the intervention group (regardless of whether they had accepted the offer of the Cytosponge-TFF3 procedure) compared with all participants in the usual care group. Based on the number who had an endoscopy following a Cytosponge-TFF3 procedure but did not have Barrett's esophagus or cancer (n=90), and on the number who successfully swallowed the Cytosponge-TFF3 but did not have Barrett's esophagus or cancer (n=1523), the researchers estimated the specificity of the Cytosponge-TFF3 procedure to detect Barrett's esophagus, dysplasia or cancer to be 94%. The authors concluded that offering Cytosponge–TFF3 testing to patients with gastroesophageal reflux improves detection of Barrett's esophagus.

Tan et al (2025) conducted the DELTA study to evaluate the real-world implementation of capsule sponge testing combined with biomarker risk stratification for surveillance of Barrett's esophagus. This prospective, multicenter UK study involved patients with non-dysplastic Barrett's esophagus who underwent both capsule-sponge testing and endoscopy. Among the 910 patients in the cohort, 138 (15%) were classified as high risk, 283 (31%) as moderate risk, and 489 (54%) as low risk according to the capsule-sponge risk stratification score. The high-risk group demonstrated a 37.7% positive predictive value for dysplasia or worse, with the highest risk observed in those with both atypia and abnormal p53 expression. In contrast, the low-risk group had a 0.4% prevalence of high-grade dysplasia or cancer and a 97.8% negative predictive value, suggesting that these patients could be safely monitored using capsule-sponge testing alone. The authors concluded that the capsule sponge risk stratification classifier enables clinicians to triage high-risk patients for earlier endoscopy while safely deferring invasive procedures for low-risk individuals.

Magnetic Capsule Endoscopy (CE)

Studies evaluating the diagnostic characteristics of magnetic CE as compared to conventional gastroscopy in the target population have generally demonstrated similar accuracy, sensitivity, and specificity, with increases in patient preference and an acceptable safety profile with the magnetic CE approach. However, the diagnostic characteristics of magnetic CE are inadequate to substitute for other modalities or to triage patients to other modalities based on the current literature. Direct evidence of improved outcomes or a strong chain of evidence to improved outcomes is lacking. The evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

Denzer et al (2015) prospectively evaluated a magnetically guided gastric capsule compared to conventional gastroscopy in 189 patients with upper abdominal complaints (e.g., upper abdominal

pain and/or anemia) from two French centers. In this first large study to evaluate magnetically guided capsule gastroscopy in patients with upper abdominal symptoms, the authors concluded that this technique was feasible in practice and clearly preferred by patients; however, further studies are needed to define its role in the clinical setting (e.g., as a filter test to stratify patients to undergo conventional gastroscopy or some other role). This non-US study reported a low sensitivity and provided an limited discussion of the types of upper abdominal complaints experienced by enrolled patients. No discussion in terms of the severity and duration of the complaints, as well as prior testing and treatment was undertaken, which makes determination of the appropriate place in therapy for magnetic CE in patients with unexplained upper abdominal complaints difficult.

Liao et al (2016) evaluated the accuracy of magnetically controlled CE as compared with conventional gastroscopy in 350 patients with upper abdominal complaints in a prospective, multicenter, blinded comparison study conducted in China. Overall, with conventional gastroscopy as the gold standard, magnetic CE detected gastric focal lesions in the entire stomach with 90.4% sensitivity, 94.7% specificity, and 93.4% accuracy. Similar sensitivity and specificity results were observed with magnetic CE as compared to conventional gastroscopy when detecting focal lesions in the upper or lower stomach specifically. No lesions of significance were missed by magnetic CE. Only five patients reported an adverse event, with the majority of these events considered to be related to gastric preparation. The authors concluded that magnetic CE detects upper abdominal focal lesions with comparable accuracy to conventional gastroscopy and is a promising alternative for screening for gastric diseases.

Meltzer et al (2023) conducted the first pilot study of magnetically controlled capsule endoscopy (MCCE) in the United States. The primary objective was to demonstrate that MCCE could visualize the major anatomic regions of the stomach in symptomatic patients before an EGD. In this prospective, single-arm, single-center, comparative study, included symptomatic adult patients (N=40) who were referred for an EGD as part of a standard evaluation. Participants received MCCE before the EGD. MCCE videos were reviewed by 2 independent physicians and compared with subsequent EGD. Patients were followed for 30 days for safety outcomes and satisfaction. Of the 40 study patients, MCCE detected each of the 6 preidentified major gastric anatomic landmarks with a greater than 95% rate of visualization. Although every capsule was able to visualize the lower esophagus, the Z-line was only visible between 78% and 85% of cases. Thirty-five patients received a follow-up EGD, and no high-risk lesions were missed with MCCE. The study is limited by the small sample size, low number of pathologic lesions, and unblinded physician interpreting results. The authors concluded that future studies need to further establish the accuracy of MCCE compared with EGD for low-risk symptomatic patients.

Motility Capsule Endoscopy

Studies assessing the utility of motility capsule testing for suspected gastric motor disorders have been limited by study design and small sample sizes. Larger, well-designed studies are needed.

Stein et al (2013) conducted a systematic review for the Agency for Healthcare Research and Quality (AHRQ). Of the 12 studies included, seven studies evaluated the diagnosis of gastric emptying delay. The strength of evidence in available studies on the ingestible capsule for assessing colonic transit

times was found to be low overall. No studies were identified that compared the SmartPill to colonic scintigraphy. Accuracy of the ingestible capsule in diagnosing slow-transit constipation was similar to tests using radiopaque markers. A moderate correlation between colonic transit times with the ingestible capsule and tests with radiopaque markers was shown in five studies (range, 0.69-0.71). The authors concluded that although the overall strength of evidence is low, data were relatively consistent and suggested that this modality is no less sensitive than conventional testing. The evidence is insufficient to determine whether use of the wireless motility capsule will improve outcomes of care.

Lee et al (2019) and Hasler et al (2019) reported findings on two large, prospective, multicenter trials that compared WMC testing with gastric emptying scintigraphy (GES) in patients with gastroparesis symptoms. Both studies found that WMC detected delayed gastric emptying more often than GES, due to WMC's capability of profiling the entire gastrointestinal tract in patients. However, the studies were limited by practice standards, participant population, and lack of correlation of physiological results with symptoms and/or management outcomes. Additional clinical studies are needed, to further investigate and compare GES versus WMC testing in patients with gastroparesis symptoms.

Sangnes et al (2020) conducted a small prospective, single center, cohort study to compare the diagnostic reliability of WMC with scintigraphy in individuals with diabetic gastroparesis, with the objective of assessing diagnostic reliability. Although the researchers reportedly found a strong correlation between WMC and 4-hour GES, the study was limited by its small study size (n = 66) and a patient cohort that may have been more severely affected by their disease.

Kuo et al (2025) conducted a multicenter, comparative, prospective cohort study to compare and evaluate the performance characteristics of the Atmo Capsule and the SmartPill Capsule (discontinued reference standard WMC) for measurement of gastric emptying time (GET) and colonic transit time (CTT) in patients with confirmed or suspected disordered gastrointestinal transit. A total of 213 participants aged 22 years or older were enrolled, each meeting at least one of the following criteria: a history of delayed GET from a prior study within the past two years and/or symptoms suggestive of gastroparesis; functional constipation per Rome IV criteria; or constipation-predominant irritable bowel syndrome per Rome IV criteria. Measurements of GET and CTT using the Atmo and SmartPill capsules were strongly correlated, with observed biases within 10% of the delayed transit margin. Delayed GET (68/177) and delayed CTT (56/147) were each identified in 38% of participants, with 84% agreement between the devices for both delayed GET (sensitivity 68%, specificity 91%) and delayed CTT (sensitivity 83%, specificity 85%). No serious adverse device effects were reported. A noted limitation of the study was the lack of diversity in the participant cohort. Additionally, due to the limited number of cases with rapid transit, the study could not assess diagnostic agreement between the devices for identifying rapid transit times. The authors concluded that this comparative prospective study demonstrated that the Atmo Capsule provides reliable measurements of GET and CTT, correlating well with the SmartPill Capsule. With the discontinuation of the SmartPill, these findings suggest that the Atmo Capsule may serve as a clinically useful and viable alternative for evaluating gastrointestinal transit.

Patency Capsule

The evidence is insufficient to determine that the technology results in an improvement in the net health outcome. The overall balance of harm and benefit of using the patency capsule cannot be determined from the existing studies.

Delvaux et al (2005) evaluated the usefulness of this system in 22 patients with suspected intestinal stenosis who were also undergoing CE. The authors stated that the current technical development of the patency capsule limits its use in clinical practice, as it did not detect stenoses undiagnosed by computed tomography (CT) or small bowel follow-through. They also stated that the start of dissolution at 40 hours after ingestion was too slow to prevent episodes of intestinal occlusion. The authors noted that patients with Crohn's disease are most likely to be at risk of blockage of progression of the capsule and should benefit from a CT investigation before CE. They noted that a careful interview eliciting the patient's medical history and symptoms remains the most useful indicator with regard to suspicion of an intestinal stenosis.

Signorelli et al (2006) evaluated 32 patients. The 26 patients who excreted the patency capsule intact, without experiencing abdominal pain, were deemed eligible for the CE procedure, which was performed uneventfully in the 25 who agreed to undergo the examination. The authors stated that the patency capsule "is an effective method for the assessment of small bowel patency before CE. However, the real incidence of complications such as the development of severe abdominal pain and small bowel obstruction needs to be ascertained before the patency test can be recommended as the standard method to evaluate patients at risk of developing capsule retention." There is a lack of data defining the safety and role of the patency capsule. Conventional evaluations remain the gold standard for ruling out any known or suspected gastrointestinal obstruction, strictures, and fistulas, prior to CE.

Kim et al (2025) conducted a systematic review and meta-analysis to evaluate the diagnostic accuracy of patency capsule (PC) and cross-sectional imaging (CSI) in predicting capsule retention (CR) during small bowel capsule endoscopy (SBCE), particularly in patients with suspected small bowel stenosis. A total of 23 studies involving 3,273 patients were included: 17 studies assessed PC (n = 3,051), four assessed CSI (n = 140), and two evaluated both PC and CSI (n = 82). The pooled sensitivity and specificity of CSI for predicting CR were 54% and 88%, respectively. In comparison, PC demonstrated a pooled sensitivity of 75% and specificity of 94%. PC showed significantly higher specificity ($p = 0.05$) and a lower pooled false-negative rate than CSI ($p = 0.001$).

PROFESSIONAL GUIDELINE(S)

Small Bowel Capsule Endoscopy

In 2017, the American Gastroenterological Association's (AGA) issued a clinical practice guideline on the use of video capsule endoscopy (Enns 2017).

- CE is recommended for patients presenting with clinical features consistent with Crohn's disease (CD), and negative ileocolonoscopy and imaging studies; for patients with CD and clinical features unexplained by ileocolonoscopy or imaging studies; in patients with polyposis syndromes, in suspected small-bowel recurrence of CD; for patients with celiac disease and unexplained symptoms despite treatment and appropriate investigations, and repeated

obscure bleeding.

- AGA recommends against CE for patients with suspected celiac disease.

The 2017 American Society for Gastrointestinal Endoscopy (ASGE) clinical guideline on the role of endoscopy in the management of suspected small-bowel bleeding suggest video CE as the initial test for patients with overt or occult small-bowel bleeding.

Refractory celiac disease management guidelines, issued by the American Gastroenterological Association's (AGA) (Green et al 2022) recommend:

- Perform small bowel imaging with capsule endoscopy and computed tomography or magnetic resonance enterography to exclude enteropathy-associated T-cell lymphoma and ulcerative jejunoileitis at initial diagnosis of type 2 refractory celiac disease (RCD2).
- Repeat imaging should be obtained in patients with RCD2 who are clinically worsening due to the increased risk of lymphoma. The presence of strictures, inflammation, erosions, ulcers, or mass lesions on capsule endoscopy or cross-sectional imaging should prompt further evaluation with small bowel enteroscopy to secure a pathologic diagnosis.

Celiac disease diagnosis and management by capsule endoscopy is not addressed in the 2023 American College of Gastroenterology (ACG) guideline update (Rubio-Tapia et al., 2023).

In 2023, the European Society of Gastrointestinal Endoscopy (ESGE) issued guideline recommendations on small-bowel capsule endoscopy and device-assisted enteroscopy for diagnosis and treatment of small-bowel disorders (Pennazio 2023).

- Recommend: small-bowel capsule endoscopy as the first-line examination, before consideration of other endoscopic and radiological diagnostic tests for suspected small-bowel bleeding. (Strong recommendation, moderate quality evidence)
- Does not recommend: routine second-look endoscopy prior to small-bowel capsule endoscopy in patients with suspected small-bowel bleeding or iron-deficiency anemia. (Strong recommendation, low quality evidence)
- Recommend: the performance of small-bowel capsule endoscopy as a first-line examination in patients with iron-deficiency anemia when small bowel evaluation is indicated. (Strong recommendation, high quality evidence)
- Recommend: small-bowel capsule endoscopy in patients with suspected CD and negative ileo-colonoscopy findings as the initial diagnostic modality for investigating the small bowel, in the absence of obstructive symptoms or known bowel stenosis. (Strong recommendation, high quality evidence)
- Recommend: in patients with established CD, the use of a patency capsule before small-bowel capsule endoscopy to decrease the capsule retention rate. (Strong recommendation, moderate quality evidence).

<u>Polyposis Syndromes</u>

In 2020, the American Society for Gastrointestinal Endoscopy (ASGE) guideline on the role of endoscopy in familial adenomatous polyposis syndromes recommends screening sigmoidoscopy or colonoscopy in suspected FAP (Yang 2020). However, the ASGE acknowledges that with the advent of CE, it has become the preferred imaging modality, because false-negative rates in contrast studies are up to 42% for polyps > 10 mm in FAP patients. When compared with magnetic resonance enterography (MRE), CE is also more sensitive for detecting smaller polyps. The 2 tests performed equally for detecting polyps >15 mm, although MRE was more reliable for determining the location and size of polyps. MRE also has the advantage of imaging outside the GI tract, including detecting desmoid tumors.

In 2022, the US Multi-Society Task Force on Colorectal Cancer (USMSTF) recommended that individuals diagnosed with Peutz-Jeghers syndrome undergo a baseline small bowel surveillance, using video CE or MRE, performed between ages 8-10 years or earlier if the patient is symptomatic (Boland et al 2022). If no polyps are found at the initial examination, surveillance should resume at age 18. (Strong recommendation, low quality of evidence).

Lynch Syndrome

The 2019 European Society of Gastrointestinal Endoscopy (ESGE) guideline on endoscopic management of Lynch syndrome and of familial risk of colorectal cancer does not address the use of capsule endoscopy (van Leerdam 2019).

Colon Capsule Endoscopy

In 2020, the European Society of Gastrointestinal Endoscopy (ESGE) and European Society of Gastrointestinal and Abdominal Radiology (ESGAR) issued updated best practice guidelines for imaging alternatives to colonoscopy: CT colonography (CTC) and colon capsule endoscopy (CCE) specific to patients undergoing screening or with suspicion of colorectal neoplasm (Spada et al., 2020). Consensus recommendations include:

- For previously incomplete colonoscopy: CCE may be considered (weak recommendation, low quality evidence).
- For patients with symptoms suggestive of colorectal cancer, but a colonoscopy is contraindicated or not possible:
    - for patients with alarm symptoms: due to a lack of evidence, CCE is not recommended in this situation (very low-quality evidence).
    - for patients without alarm symptoms: CCE may be considered (weak recommendation, low quality evidence).
- For colorectal cancer screening: CCE is not suggested as a first-line screening test (weak recommendation, low quality evidence).
- There is insufficient evidence to recommend CCE for:
    - following curative-intent resection of colorectal cancer,
    - surveillance after polypectomy,

The 2021 American College of Gastroenterology (ACG) clinical guidelines for colorectal cancer screening suggest consideration of the colon capsule for screening [conditional recommendation; very low quality] (Shaukat et al., 2021).

The 2021 U.S. Preventive Services Task Force (USPSTF) final recommendation statement for colorectal cancer screening specifically indicates that USPSTF recommendation does not include capsule endoscopy for colorectal cancer screening due to limited available evidence on these tests and because other effective tests (i.e., the recommended screening strategies) are available.

The 2025 National Comprehensive Cancer Network (NCCN version 2.2025) clinical practice guidelines for colorectal cancer screening do not include capsule endoscopy as an image-based colorectal cancer screening modality. However, NCCN footnotes state, "for patients who have had incomplete colonoscopy, consider CE as alternative exam for completing the screening."

GI Bleed Detection Capsule Endoscopy

There are currently no recommendations from professional medical societies supporting the use of GI bleed detection capsule endoscopy for any clinical indication.

Esophageal Capsule

The 2019 American Society for Gastrointestinal Endoscopy (ASGE) guidelines on screening and surveillance of Barrett's esophagus (BE) acknowledge the significant potential of emerging screening technologies beyond standard upper endoscopy. These include esophageal capsule endoscopy, Cytosponge (Medtronic), tethered capsule endomicroscopy, and electronic nose devices. However, the ASGE panel ultimately endorsed screening for BE in at-risk populations based on the available evidence regarding BE prevalence in specific groups.

The 2022 clinical practice update from the American Gastroenterological Association (AGA) on new technologies for BE screening and surveillance reaffirmed that upper endoscopy with biopsies remains the gold standard for diagnosing BE (Muthusamy, 2022). Nonetheless, the AGA issued best practice advice supporting the consideration of nonendoscopic cell-collection devices—such as Cytosponge (Medtronic GI Solutions), EsoCheck (Lucid Diagnostics), and EsophaCap (Capnostics)—as screening options for BE. While all three devices have demonstrated excellent tolerability, safety, and sensitivity for BE diagnosis, the AGA emphasized the need for further data to validate patient selection criteria and determine the optimal settings for their use in the United States.

The 2023 European Society of Gastrointestinal Endoscopy (ESGE) guidelines on the diagnosis and management of Barrett esophagus (BE) recommends that a swallowable non-endoscopic cell collection device (e.g., Cytosponge) can be used as an alternative to endoscopy for case finding of Barrett's esophagus (strong recommendation, high quality evidence) (Weusten et al., 2023). The recommendation was based on findings from observational case-controlled studies and one randomized controlled trial.

Magnetic Capsule Endoscopy (CE)

There are currently no recommendations from professional medical societies supporting the use of magnetic capsule endoscopy for any clinical indication.

Motility Capsule Endoscopy

In 2021, the United European Gastroenterology (UEG) and European Society for Neurogastroenterology and Motility (ESNM) consensus on gastroparesis did not endorse the statement that wireless motility capsule (WMC) assessment is a valid test of diagnosing gastroparesis [Grade B recommendation] (Schol 2021). Noting the pitfall with WMC is that it is an indigestible solid and, therefore, it empties from the stomach in response to phase 3 migrating motor complexes rather than with the test meal.

The 2022 American Gastroenterological Association (AGA) expert review clinical practice update on management of medically refractory gastroparesis reiterated the EUG/ESNM consensus concern that because the WMC, an inanimate object, identifies the phase III activity front of the migrating motor complex rather than overall gastric emptying, a meal-based test provides better physiological assessment of gastric emptying and is thus recommended as the first-line test of gastric emptying over the WMC (Lacy 2022).

The American College of Gastroenterology (ACG) updated clinical guidelines on gastroparesis recommends scintigraphy gastric emptying (SGE) as the standard test for the evaluation of gastroparesis in patients with upper GI symptoms (strong recommendation, moderate level of evidence) (Camilleri 2022). The ACG reports that research supports WMC testing as an alternative test to SGE for the evaluation of gastroparesis in patients with upper GI symptoms and made a conditional recommendation (low quality of evidence) that WMC testing may be an alternative to the SGE assessment.

Patency Capsule

The 2017 American Gastroenterological Association (AGA) clinical practice guidelines for the use of video CE states "In patients with known or suspected strictures of the small bowel, we suggest a patency capsule before CE to minimize risk of retention. (GRADE: Conditional recommendation, very low-quality evidence for efficacy, low-quality evidence for safety)." (Enns 2017).

The 2023 European Society of Gastrointestinal Endoscopy (ESGE) guideline on small-bowel capsule endoscopy and device-assisted enteroscopy for diagnosis and treatment of small-bowel disorders recommends, in patients with established Crohn's disease, the use of a patency capsule before small-bowel capsule endoscopy to decrease the capsule retention rate (Pennazio 2023). (Strong recommendation, moderate quality evidence).

REGULATORY STATUS

The U.S. Food and Drug Administration (FDA) regulates capsule endoscopy systems as medical devices. All capsule endoscopy systems including related components require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2025 Sep 17].

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most

serious type of recalls. on our website by the date that the FDA posts the information on our website. Available from: https://www.fda.gov/medical-devices/medical-device-safety/medical-device-recalls [accessed 2025 Sep 17].

The FDA has cleared several capsule endoscopy devices, including but not limited to devices that visualize small bowel mucosa (e.g., PillCam SB2 and SB3), esophageal mucosa (e.g., PillCam ESO), the colon (e.g., PillCam COLON), and the stomach (e.g., NaviCam Stomach Capsule System). In addition, the FDA has cleared capsules for other diagnostic purposes, such as verifying GI patency (e.g., PillCam Patency Capsule), measuring gastrointestinal transit time (e.g., Atmo Gas Capsule), and detecting the presence of blood in the GI tract (e.g., PillSense System).

Small Bowel Capsule Endoscopy

The Given Diagnostic Imaging System, PillCam SB, received initial Section 510(k) marketing clearance from the FDA on August 1, 2001. The FDA cleared the device for use along with, not as a replacement for, other endoscopic and radiologic evaluations of the small bowel. On July 2, 2003, the FDA approved the PillCam SB as a first-line tool in the detection of abnormalities of the small bowel, removing the adjunctive tool qualifier. On October 29, 2003, the FDA announced that it had expanded its approved indications for the use of wireless CE, PillCam SB, to include visualization of the small bowel and detection of abnormalities in symptomatic children aged 10 to 18 years. This approval was based on data from a small trial where the wireless CE was able to diagnose or definitively exclude a bleeding source, small bowel polyps or Crohn's disease in 29 out of 30 children. In September 2009, the FDA expanded its approval of the PillCam SB for use in children aged two years and up.

The Olympus Capsule Endoscope System received Section 510(k) marketing clearance from the FDA in September 2007, as equivalent in intended use, method of operation, material, and design to the predicate device (PillCam SB). It is used for visualization of the small intestine mucosa. FDA approval was based upon a study of 51 patients with OGIB who swallowed both the PillCam SB and the Endocapsule, 40 minutes apart and in randomized order. The devices were similar, in terms of the detection of normal versus abnormal small intestine mucosa and in their diagnostic capability (Cave et al., 2008).

Ingestible Esophageal Capsule

The PillCam ESO (Given Imaging) was approved by the FDA in November 2004 as a non-invasive alternative to endoscopy, to diagnose and evaluate diseases of the esophagus. Direct imaging of the small bowel with an endoscope is limited, and, thus, wireless CE of the small bowel occupies a unique diagnostic niche. In contrast, esophageal endoscopy, which also offers the opportunity for biopsy, is a routinely performed procedure. Therefore, assessment of CE of the esophagus requires comparison of its diagnostic performance to the gold standard of conventional endoscopy. One proposed indication for the capsule camera is detection of Barrett's esophagus, considered a premalignant condition associated with gastroesophageal reflux disease (GERD). Conventional endoscopy is often recommended in patients with longstanding symptoms of GERD, or in those requiring pharmacologic therapy to control GERD symptoms, to rule out Barrett's esophagus. This is a high-volume indication for conventional upper endoscopy, given the high prevalence of GERD.

Colon Capsule Endoscopy

Given Imaging received FDA Section 510(k) clearance (Class II) for the PillCam COLON 2 in February 2014. The clearance is intended for use in patients who had an incomplete traditional colonoscopy and still require a better review of the passageway.

Patency Capsule

The FDA approved the Agile patency capsule in May 2006 as an accessory to the Pill Cam video capsule, intended to verify adequate patency of the gastrointestinal tract prior to administration of the Pill Cam video capsule in patients with known or suspected strictures. Medtronic replaced the Agile Patency System with an updated product, PillCam Patency Capsule, which was FDA cleared in 2018.

Motility Capsule Endoscopy

In 2006, the ingestible capsule (SmartPill GI Monitoring System) was FDA-cleared through the Section 510(k) process for the evaluation of delayed gastric emptying. In 2009, the FDA expanded the use of the SmartPill to determine colonic transit time for the evaluation of chronic constipation and to differentiate between slow and normal transit constipation. The SmartPill motility capsule was discontinued in June 2023.

The Atmo Gas Capsule (Atmo Biosciences, Ltd) received FDA premarket approval in June 2025. The capsule measures whole gut and regional gut (stomach, small bowel, and colon) transit times for the evaluation of patients with suspected gastroparesis, and it not for use in pediatric patients.

Magnetic Capsule Endoscopy (CE)

The FDA approved a novel magnetically maneuvered CE system, NaviCam (AnX Robotica, Inc.) in May 2020. The device is contraindicated for use in patients with gastrointestinal obstruction, stenosis, fistula, or those with dysphagia. Other contraindications include patients with cardiac pacemakers or other implantable electronic medical devices as well as pregnant women, those less than 22 years of age, and those with a body mass index of 38 or greater.

Blood Detection Capsule Endoscopy

In February 2023, the FDA approved a novel ingestible GI blood detection capsule, PillSense System (EnteraSense) intended to be used as an adjunct, not a standalone diagnostic device, for clinical decision making. The device is a single-use ingestible capsule uses spectrophotometry (light absorption technology) to detect blood in the upper gastrointestinal tract as wirelessly transmits data to an external receiver.

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational

- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
91110	Gastrointestinal tract imaging, intraluminal (e.g., capsule endoscopy), esophagus through ileum, with interpretation and report
91111	Gastrointestinal tract imaging, intraluminal (e.g., capsule endoscopy), esophagus with interpretation and report
91112 (E/I)	Gastrointestinal transit and pressure measurement, stomach through colon, wireless capsule, with interpretation and report
91113 (E/I)	Gastrointestinal tract imaging, intraluminal colon (e.g., capsule endoscopy), with interpretation and report
91299 (*E/I)	Unlisted diagnostic gastroenterology procedure *E/I when billed as use of patency capsule and blood detection capsule
0651T (E/I)	Magnetically controlled capsule endoscopy, esophagus through stomach, including intraprocedural positioning of capsule, with interpretation and report
0977T (E/I)	Upper gastrointestinal blood detection, sensor capsule, with interpretation and report (Effective 07/01/25)

MEDICAL POLICY

Medical Policy Title	**Cardiac Rehabilitation**
Policy Number	**8.01.14**
Current Effective Date	**August 1, 2026**
Next Review Date	**October 2026**

Our medical policies are based on the assessment of evidence based, peer-reviewed literature, and professional guidelines. Eligibility for reimbursement is based upon the benefits set forth in the member's subscriber contract. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Monitored Phase I and Phase II cardiac rehabilitation (CR) programs are considered **medically appropriate** for **ANY** of the following indications:

   A. Acute myocardial infarction (MI) within the preceding 12 months;

   B. Percutaneous coronary intervention (i.e., percutaneous transluminal coronary angioplasty (PTCA), atherectomy, stenting) within the preceding 12 months;

   C. Coronary bypass surgery within the preceding 12 months;

   D. Heart transplantation within the preceding 12 months;

   E. Class II or higher congestive heart failure;

   F. Stable angina pectoris;

   G. Valvular disease.

II. Additional CR services are considered **medically appropriate** if the individual has another qualifying cardiac event, including **ANY** of the following:

   A. Another documented MI or extension of initial infarction;

   B. Another cardiovascular surgery or percutaneous intervention;

   C. New, clinically significant coronary lesions documented by cardiac catheterization.

III. Phase III maintenance programs are considered **not medically necessary**. (Please refer to Policy Guideline IV).

IV. Intensive cardiac rehabilitation (ICR), is considered **investigational** for **ALL** indications, including but not limited to, the following programs:

   A. The Ornish Program for Reversing Heart Disease;

   B. The Pritikin Program;

   C. The Benson-Henry Institute Cardiac Wellness Program.

Inpatient Physical Rehabilitation: Acute, Subacute & Skilled 1370/20.000204

POLICY GUIDELINE(S)

I. Cardiac rehabilitation for pediatric patients will be reviewed based on clinical indicators, including, but not limited to the patient's diagnosis (e.g., congenital anomalies, valvular disorders), recent surgical procedures (e.g., cardiac transplant, valvular replacement, or repair), and acceptance into a pediatric cardiac rehabilitation program.

II. Monitored Phase II cardiac rehabilitation programs must be recommended by the patient's cardiologist or primary care physician and rendered by a provider whose cardiac rehabilitation program has been approved by:

   A. the American Association of Cardiovascular and Pulmonary Rehabilitation (AACVPR), if the program is rendered at an outpatient free-standing facility or in the practitioner's office; or

   B. the AACVPR, the Joint Commission on Accreditation of Healthcare Organizations (JCAHO), or the American Osteopathic Association (AOA), if the program is rendered at a hospital-based facility.

III. Due to the increased risk of experiencing a cardiac event (e.g., ventricular arrhythmia, infarction), Phase II CR programs must include physician supervision and continuous electrocardiographic monitoring during exercise.

IV. Phase III maintenance programs consist of activities that preserve the patient's present level of function and prevent regression of that function. Maintenance begins when the therapeutic goals of a treatment plan have been achieved or when no additional functional progress is apparent or expected to occur.

DESCRIPTION

Cardiac rehabilitation services are comprehensive, long-term programs involving medical evaluation, prescribed exercise, cardiac risk factor modification, education, and counseling. These programs are designed to limit the physiologic and psychological effects of cardiac illness, reduce the risk for sudden death or re-infarction, control cardiac symptoms, stabilize or reverse the atherosclerotic process, and enhance the psychosocial and vocational status of selected patients.

A CR program should be initiated as soon as medically indicated following a cardiac event. Examples of cardiac events are acute MI, coronary artery bypass graft, percutaneous transluminal coronary angioplasty (PTCA), heart valve surgery, heart transplantation, stable angina pectoris, or compensated heart failure.

CR consists of three phases, or levels, of service:

I. Phase I, or inpatient CR: a program that delivers preventive and rehabilitative services to hospitalized patients following an index cardiovascular disease (CVD) event.

II. Phase II, or early outpatient CR: a physician-supervised outpatient program that includes electrocardiographic monitoring during exercise and is intended to improve cardiac function and exercise tolerance. Programs are hospital, physician's office- or clinic-based and must meet federal and state regulatory and licensing requirements; and

III. Phase III, or long-term outpatient CR: a supervised or non-supervised maintenance program.

CR program providers are subject to state and federal licensing requirements. Due to the advances in the diagnosis and treatment of cardiac disease, there is a shift of CVD from an acutely fatal event to a chronic disease. There is a growing need for medical services to aid patients in improving their quality of life, lessen symptoms, increase functional capacity, and decrease disability. Formal CR programs meet this need for select cardiac patients and improve their net health outcomes by decreasing the incidence of cardiac death.

Intensive Cardiac Rehabilitation

According to the Centers for Medicare and Medicaid Services (CMS), ICR refers to a physician-supervised program that furnishes CR services more frequently, and often in a more rigorous manner. As required by §1861(eee)(4)(A) of the U.S. Social Security Act (the "Act"), an ICR program must demonstrate, through peer-reviewed, published research, that it accomplished one or more of the following for its patients:

I. Positively affected the progression of coronary heart disease (CHD);

II. Reduced the need for coronary bypass surgery; or

III. Reduced the need for percutaneous coronary interventions.

The ICR program must also demonstrate, through peer-reviewed, published research, that it accomplished a statistically significant reduction in five (5) or more of the following levels for patients, measured from before CR services to after CR services:

I. Low-density lipoprotein;

II. Triglycerides;

III. Body mass index;

IV. Systolic blood pressure;

V. Diastolic blood pressure; and

VI. the need for cholesterol, blood pressure, and diabetes medications.

ICR program sessions are limited to 72 one-hour sessions, up to six sessions per day, over a period of up to 18 weeks. There is no standard definition of an ICR program and, thus, specific programs are reviewed individually.

SUPPORTIVE LITERATURE

Sumner et al (2017) published a systematic review of controlled observational studies evaluating CR in patients diagnosed with acute MI. CR interventions consisted of structured, multi-component programs that included exercise and at least one of the following: education, information, health behavior change, and psychological or social support. Usual care interventions, generally supervised medical interventions, were the control conditions. Ten studies met reviewers' eligibility criteria. In a meta-analysis of five studies reporting all-cause mortality (an unadjusted outcome), there was a significantly lower risk of death in the group that received CR (odds ratio, 0.25; 95% CI, 0.16 to 0.40). Three studies that reported an adjusted analysis of all-cause mortality also found a significant benefit from CR (odds ratio, 0.47; 95% CI, 0.38 to 0.59). Similarly, a meta-analysis of three studies reporting cardiac-related mortality (an unadjusted analysis) found a significant benefit from CR (odds ratio, 0.21; 95% CI, 0.12 to 0.37). Only one study reported an adjusted analysis of cardiac-related mortality, so data could not be pooled.

Nilsson et al (2018) investigated the effect of a 12-week CR program with a high-intensity interval exercise component using participant VO2peak as a measure of improved exercise capacity. Increased exercise capacity has been shown to improve survival among persons with CHD. The objective of the study was to assess whether this addition to a CR program yielded improved long-term results. A total of 133 coronary patients participated in this prospective cohort study and were evaluated at baseline, at the end of the 12-week program, and again at a 15-month follow-up. Additional test measurements included a cardiopulmonary exercise test, body mass index, blood pressure tests, and a quality of life questionnaire. Of the 133 patients, 86 patients had complete information for the 15-month follow-up. Mean VO2peak improved from a baseline of 31.9 mL/kg/min to 35.9 mL/kg/min ($p<0.001$) at the end of the 12-week program, and to 36.8 mL/kg/min (CI not reported) at 15-month follow-up. Most of the 86 patients reported maintaining an exercise routine. Study limitations included the small sample size, a relatively low-risk male population at baseline, and lack of information on the qualifying event for CR. The authors concluded that the CR program intervention potentially fostered consistent and beneficial exercise habits, as demonstrated by improved VO2peak.

The benefits of formal CR programs outweigh those of informal exercise programs or the lack of a rehabilitative program. Through clinical trials, supervised/formal CR programs have been proven to improve the health outcomes of select cardiac patients.

Intensive Cardiac Rehabilitation

Ornish et al (1990) conducted a randomized, controlled trial (RCT), called the Lifestyle Heart Trial, comparing a version of the Ornish Program for Reversing Heart Disease with usual care. Initial results were reported in 1990, and five-year results in 1998. Twenty (71%) of 28 patients in the intervention group and 15 (75%) of 20 in the control group completed the five-year follow-up. The intervention and control groups did not differ significantly in the number of MI events (2 versus 4), CABGs (2 versus 5), or deaths (2 versus 1). However, compared with the control group, the intervention group had significantly fewer percutaneous transluminal coronary angioplasties (8 versus 14, $p<0.050$) and cardiac hospitalizations (23 versus 44, $p<0.001$). The trial had a small sample size for a cardiac trial (N=48), and only 35 patients were available for the five-year follow-up.

Lakhani et al. (2023) conducted a prospective, nonrandomized study that compared intensive cardiac rehabilitation with the Pritikin Program and traditional outpatient cardiac rehabilitation. The primary outcomes of interest were change in diet quality and quality of life from baseline to visit 24. There was a significant improvement in diet quality but not in quality of life between the Pritikin Program and traditional cardiac rehabilitation groups. Body mass index was also improved in patients who received intensive rehabilitation. Limitations of the study include a short follow-up, lack of data for cardiovascular outcomes, and nonrandomization.

Racette et al (2022) published seven-year outcomes from the first institution to implement the Pritikin Program. Retrospective data for 1,507 patients who received the intensive cardiac rehabilitation program and 456 patients who received traditional cardiac rehabilitation were compared. Outcomes of interest (e.g., anthropometric measures, dietary patterns, 6-minute walk distance [6MWD], grip strength, and HRQoL) all improved with the Pritikin Program. Significant benefit of the Pritikin Program compared to traditional cardiac rehabilitation were noted for change in body weight ($p<.0001$), body mass index ($p<.0001$), waist circumference ($p<.0001$), and diet quality as measured by the Rate Your Plate score ($p<.0001$). There was no difference in 6MWD or grip strength between groups. Cardiovascular outcomes, including rehospitalization or mortality, were not assessed and there was no follow up on the patients who did not complete the program.

No RCTs have evaluated the Pritikin Program or the Benson-Henry Institute Cardiac Wellness Program, in comparison to usual care or to standard CR; therefore, conclusions cannot be drawn for these programs regarding their impact on health outcomes.

PROFESSIONAL GUIDELINE(S)

The American College of Cardiology (ACC), American Heart Association (AHA), American College of Emergency Physicians (ACEP), National Association of EMS Physicians (NAEMSP) and Society for Cardiovascular Angiography and Interventions (SCAI) published guideline for the management of patients with acute coronary syndromes (Rao 2025). Their recommendations regarding cardiac rehabilitation state:

- "Patients with ACS should be referred to an outpatient CR program prior to hospital discharge to reduce death, myocardial infarction, hospital readmissions, and improve functional status and quality of life (Class 1; LOE A)."
- "In patients with ACS, a home-based CR program is a reasonable alternative to a center-based CR program to improve functional status and QOL (Class IIa; LOE BR)."

The AHA and the American Association of Cardiovascular and Pulmonary Rehabilitation (AACVPR) published a scientific statement addressing the core components of CR and secondary prevention programs (Brown 2024). The core components included patient assessment before beginning the program, nutritional counseling, weight management and body composition, blood pressure management, lipid management, diabetes management, tobacco cessation, psychosocial management, aerobic exercise training, strength training, physical activity counseling, and program quality. Programs that only offered supervised exercise training were not considered cardiac rehabilitation.

The AHA and ACC published a scientific statement regarding the supervised exercise training for chronic heart failure with preserved ejection fraction (Sachdev 2023). Their findings include the following:

- "Current guidelines also include a Class 1 recommendation (Level of Evidence A) for exercise training in patients with HF."
- "To the best of our knowledge, only 4 trials of home-based exercise training for patients with chronic HF have been published. All reported improved exercise capacity and quality-of-life metrics. However, because of the short duration (3–6 months) and small number of exercising subjects (n=67) included, the safety and efficacy of these training regimens remain unproven."

The AHA, ACC, and the Heart Failure Society of America (HFSA) published clinical practice guidelines for the management of heart failure (Heidenreich 2022). They recommend:

- "A cardiac rehabilitation program for patients with HF usually includes a medical evaluation, education regarding the importance of medical adherence, dietary recommendations, psychosocial support, and an exercise training and physical activity counseling program. Patients with HF on optimal [goal directed medical therapy] GDMT, who are in stable medical condition and are able to participate in an exercise program, are candidates for an exercise rehabilitation program."
- "For patients with HF who are able to participate, exercise training (or regular physical activity) is recommended to improve functional status, exercise performance, and QOL."
- "In patients with HF, a cardiac rehabilitation program can be useful to improve functional capacity, exercise tolerance, and health related QOL."

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgment when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

Background

Sickle Cell Disease

Sickle cell disease (SCD) refers to a group of inherited blood disorders that are caused by a mutation in the β-globin gene, causing abnormal hemoglobin properties. The mutant hemoglobin is susceptible to continuous polymerization with other hemoglobin molecules in hypoxic environments. As the mutated hemoglobin (HbS) polymerizes, the red blood cell becomes deformed; rigid and inflexible in a "sickle" shape which leads to vaso-occlusion and hemolysis severely affecting blood flow in these patients. Incidence of sickle cell disease is estimated at 300,000 to 400,000 live births throughout the world. It is estimated that 100,000 people are living with SCD in the United States. [1]

Hallmark manifestations of SCD include recurrent vaso-occlusive events or crises (VOEs or VOCs) which can lead to acute pain crises. Vaso-occlusive crises can lead to episodes of severe pain from decreased blood flow in microcapillaries and can include blood vessel blockage that can lead to tissue ischemia of the bone and bone marrow. These can lead to an increase in hospitalizations, and underlying medication complications such as severe infections, acute chest syndromes (ACS), acute splenic sequestration crisis, priapism, and stroke. There are several subtypes of SCD that exist that are determined by specific mutations in each hemoglobin gene. Severe SCD genotypes are listed as: βS/βS, βS/β0, and βS/β+. However, the available treatments that have been created thus far are independent of these subtypes.

America Society of Hematology guidelines recommend treating SCD based on need of complication. Guidelines exist for sickle cell disease with cardiopulmonary and kidney disease, transfusion support, cerebrovascular disease, management of acute and chronic pain, and stem cell transplantation.

Historically, Hydroxyurea has been the mainstay of treatment in SCD. This medication increases red blood cell fetal hemoglobin to reduce the amount of "sickled" cells being produced. Other available and FDA approved treatments for SCD include Endari (L-glutamine), Adakveo (crizanlizumab), and Oxybryta (voxelotor). Other interventions include hematopoietic stem cell transplantation (HSCT) which has shown to be curative in some individuals but depends on patient specific factors and compatible donor availability. Blood transfusions, and packed red blood cells may help as adjunctive therapy in unblocking blood vessels by delivering oxygen to the body. Stem cell gene therapy interventions are emerging for SCD and may offer a curative treatment for its complications.

Beta Thalassemia

Thalassemias are inherited hemoglobinopathies in which impaired production of one type of globin chain; either alpha or beta, causes an imbalance in the ratio between those chains. These chains precipitate and cause significant cellular damage, thus causing issues with red blood cell maturation and leads to ineffective erythropoiesis, hemolytic anemia, iron overload, and ensuing complications. Specifically in beta-thalassemia, this impaired production is caused by mutations in the hemoglobin beta globin gene. There are more than 350 beta-thalassemia mutations currently known, and while distinction of the various phenotypes of thalassemia is mostly based on clinical parameters, genotype-phenotype associations are commonly established. There are four different phenotypes in beta-thalassemia: Major, intermedia, trait/minor, and silent carriers. However, in terms of treatment, individuals with beta thalassemia are classified as either being transfusion dependent (TDT) or non-transfusion dependent (NTDT).

Transfusion dependent individuals are those patients that require regular, life-long transfusions to mitigate severe anemia and extramedullary hematopoiesis. This classification does not include those patients who only periodically require transfusions for anemia, but they may become fully transfusion dependent over time. Non-transfusion dependent individuals do not require regular transfusions.

Whichever the category a patient falls into, the management of beta thalassemia mainly involves treating the anemia if it is severe enough to cause symptoms, reducing ineffective erythropoiesis, preventing excess iron stores from forming, and treating the complications of such iron overload if it occurs. Both TDT and NTDT are fluid categories based on clinical parameters, and a patient can switch from one group to the other over the course of their lives. As such, these designations should primarily represent a patient's current clinical status.

If iron overload occurs from the frequent transfusions, it can cause organ toxicity and potentially mortality. In this case, it may be necessary to use iron chelation therapy to remove excess iron from the body. Currently, there are three iron chelating agents on the market for iron overload: deferasirox, deferiprone, and deferoxamine. No single agent is considered the "gold standard," and long-term randomized, prospective studies for this comparison are lacking. However, all three are approved for the treatment of iron overload in transfusion-

dependent thalassemia, and the choice of agent is largely dependent on preference of the prescriber and patient, patient age, comorbidities, and side effect profile.

Potentially curative treatment for beta-thalassemia was hemopoietic stem cell transplant from an HLA-matched donor as well as betibeglogene autotemcel (beti-cel) gene therapy. Beti-cel is a promising type of curative treatment for those with beta-thalassemia, and it is used to introduce new genes or edit existing genes in hematopoietic stem cells to reduce the frequency of blood transfusions. Betibeglogene autotemcel has yielded results in five studies, two phase 1/2 trials, 2 phase 3 trials (of which 89% of participants achieved transfusion dependence), and one long-term follow up cohort study of trial participants.

Casgevy (Exagamglogene autotemcel)
Casgevy *(exagamglogene autotemcel)* is an autologous genome edited hematopoietic stem cell-based gene therapy approved for use in patients 12 years and older with sickle cell disease (SCD) with recurrent vaso-occlusive crises (VOCs) and transfusion-dependent β-thalassemia (TDT). Casgevy uses clustered regularly interspaced palindromic repeats (CRISPR)/CRISPR-associated protein 9 (Cas9)–based gene editing. This technology allows for targeted manipulation of specific genes. In the case of SCD, Casgevy targets the BCL11A gene to reduce its expression and ultimately increase fetal hemoglobin (HbF) and γ-globin production. Elevated levels of fetal hemoglobin (HbF) have been associated with improved morbidity and mortality in patients with SCD and TDT. Typically, infants and neonates are asymptomatic due to elevated fetal hemoglobin levels and begin to show symptoms after HbF synthesis declines within the first year of life.[7-9] In TDT, the increase in γ-globin alleviates the imbalance between α-globin and non-α-globin chains resulting in improved erythropoiesis and hemoglobin levels and ultimately transfusion independence.

SCD Clinical Study Experience
In a single phase I/II/III trial of exa-cel (CLIMB-121 trial) there were 35 participants with only 17 participants having had 12 months of follow up for the primary study outcome. Of those 17 participants, 16 (94.1%) were free of severe VOEs/VOCs during that time. The clinical trial for exa-cel has defined severe VOCs as:

- Acute pain that requires a visit to a medical facility and administration of pain medications (opioids, or IV NSAIDs) or RBC transfusions
- ACS, as indicated by presence of new pulmonary infiltrate associated with pneumonia-like symptoms, pain, or fever
- Priapism lasting more than two hours
- Splenic sequestration

The Institute for Clinical and Economic Review (ICER) reviewed Exa-Cel as part of a review titled, "Gene Therapies for Sickle Cell Disease." In both trials for lovo-cel and exa-cel, there were serious adverse events observed. These serious adverse effects are attributed to the myeloablative conditioning however were not infrequent and both therapies require chemotherapy before receiving them. ICER noted that uncertainly still remains about the long-term degree of risk of gene therapies in the real word. Exa-cel has its own concerns, with the small number of patients treated, short median follow-up time in CLIMB-121, and that CRISPR therapy is even newer than lentiviral gene therapy. **ICER noted that in those with severe SCD, compared with standard of care, treatment with exa-cel may be comparable, result in incremental net benefit, or result in substantial net benefit (rating C++, comparable or better).**

TDT Clinical Study Experience
This study was an ongoing ((NCT03655678) at least 24 months after treatment) open-label, multi-center, single-arm trial evaluating exa-cel in those with transfusion-defendant beta-thalassemia. For those treated, after 24 months, those subjects were encouraged to enroll in a follow-up trial, for a 15 year follow up (NCT04208529). Eligibility for this study included a history of requiring at least 100 mL/kg/year or 10 units/year of RBC transfusions in the two years prior to enrollment. At the time of the interim analysis, 59 subjects were enrolled in the trial, of which 88% (n-52) received therapy and formed the full analysis set (FAS). From the FAS population, 67% had adequate follow-up to allow for primary efficacy endpoint analysis (primary efficacy set or PES). The primary outcome was the proportion of patients achieving transfusion independence for 12 consecutive months (**TI12**), defined as maintaining weighted average Hb ≥ 9 g/dL without RBC transfusions for at least 12 consecutive months any time within the first 24 months after infusion, evaluated starting 60 days after the last RBC transfusion for post-transplant support or TDT disease management. The TI12 responder rate was 32/35 (91.4%, 98.3% one-sided CI: 75.7%, 100%). All patients who achieved TI12 remained transfusion-independent, with a median (min, max) duration of transfusion-independence of 20.8 (13.3, 45.1) months and normal mean weighted average total Hb levels (mean [SD] 13.1 [1.4] g/dL). The median (min, max) time to last RBC transfusion for patients who achieved TI12 was 30 (11, 91) days following infusion. Three patients did not achieve TI12. These patients had reductions in annualized RBC transfusion volume requirements of 79.8%, 83.9%, and 97.9%, and reductions in annualized transfusion frequency of 78.6%, 67.4%, and 94.6%, respectively, compared to baseline requirements.

Summary	
Effective Date of Policy	7/14/2026
Indications	Sickle Cell Disease (D57), transfusion-dependent β-thalassemia (TDT) (D56.1)
Availability	See FDA Prescribing Information
HCPCS Code	J3392
Duration	Authorization will be for 6 months to allow sufficient time for administration

Required Criteria for Initial Approval		
All of the following conditions for the requested indication must be met in order to approve therapy		
Indication	**Inclusion Criteria**	**Recommended Dosing**

Treatment of patients aged 2 years and older with sickle cell disease (SCD) with recurrent vaso-occlusive crises (VOCs)
(FDA Approved)
	• Enrollee is ≥ 2 years of age
	• Therapy is requested by a hematologist or prescriber with expertise in the management of Sickle Cell Disease
	• Must have documentation of all of the following:
	  ○ Patient has a confirmed diagnosis of sickle-cell disease with one of the following βS/βS or βS/β0 or βS/β+ genotype. Additional genotypes will be considered on a case-by-case basis based on disease severity AND
	  ○ History of at least 2 severe vaso-occlusive events or crises (VOCs/VOEs) per year over the last 2 years. Severe VOC/VOE is defined as at least ONE of the following:
	  ▪ Acute pain episode that requires a visit to a medical facility and administration of pain medications (opioids or IV NSAIDs) or RBC transfusions OR
	  ▪ Acute chest syndrome (ACS), as indicated by presence of new pulmonary infiltrate associated with pneumonia-like symptoms, pain, or fever OR
	  ▪ Hepatic sequestration OR
	  ▪ Priapism lasting more than 2 hours and leading to a medical-facility visit
	• Must have experienced ONE of the following pertaining to hydroxyurea (1, 2, or 3):
	  ○ 1. A therapeutic failure (ex. continued frequent and/or severe VOCs or ongoing, frequent transfusion requirements) to a ≥ 6 consecutive month trial of hydroxyurea at maximum tolerated dosing. Adherence will be assessed based on:
	  ▪ Pharmacy refill history. If the patient does not have pharmacy benefits through this health plan, a recent pharmacy profile will be requested. Progress notes documenting usage of sample medication may also be requested OR
	  ○ 2. A contraindication to hydroxyurea defined as a hypersensitivity to hydroxyurea or any component of the formulation OR
	  ○ 3. Experienced two hematologic toxicity reactions with hydroxyurea that resulted in discontinuation of therapy
	  ▪ Hematologic toxicity with hydroxyurea is defined by neutrophil, platelet, hemoglobin and/or reticulocyte count abnormalities concurrent with hydroxyurea use suggestive of hematologic toxicity. After the first hematologic toxicity, hydroxyurea therapy should be stopped and can be restarted with a dose reduction upon hematologic recovery. If a second hematologic toxicity is experienced, treatment should be discontinued
	• Must have Karnofsky performance status of ≥ 80% for patients ≥ 16 years of age or Lansky performance status of ≥ 80% for patients < 16 years of age
	• Must be used as a single agent therapy (not applicable to myeloablative conditioning therapy)
	• Enrollee has been screened and found negative for active infections of the following: hepatitis B virus (HBV), hepatitis C virus (HCV), and human immunodeficiency virus 1 &2 (HIV-1/HIV-2) in accordance with clinical guidelines prior to collection
		• The minimum recommended dose of Casgevy is 3 × 10^6 CD34+ cells/kg and will be approved as a one-time dose
		• Please refer to Casgevy FDA-approve prescribing information for complete dosage and administration instructions
		• Casgevy is for autologous use only

	of cells (documentation of laboratory results taken within the past 3 months is required • Enrollee will not receive concomitant therapy with any of the following: o Iron chelators for 7-days prior to mobilization and 6 months post-treatment (3-months post-treatment for non-myelosuppressive iron chelators) AND o Disease-modifying agents (e.g., voxelotor, crizanlizumab, L- glutamine) for at least 8-weeks prior to mobilization AND o Hydroxyurea for at least 2 months prior to mobilization • Enrollee must be eligible to undergo hematopoietic stem cell transplant (HSCT) • Prescriber must attest that the patient will not be re-started on hydroxyurea or other disease modifying therapies for SCD after receipt of Casgevy	
Treatment of patients aged 2 years and older with transfusion-dependent β-thalassemia (TDT) **(FDA Approved)**	• Enrollee is ≥ 2 years of age • Therapy is prescribed by a hematologist or provider who specializes in management of beta thalassemia • Enrollee has documented diagnosis of Transfusion Dependent Beta Thalassemia with genetic confirmation of the following: o Non-β0/β0 genotype (i.e., β0/β+, βE/β0, and β+/β+) OR o β0/β0 genotype (other examples include: β0/β+(IVS-I-110) and β+(IVS-I-110)/β+(IVS-I-110)) • Clinical documentation supports the enrollee has had the following in the previous two years (one of the below two options): o Receipt of ≥ 10 transfusions of packed red blood cells (pRBC) per year OR o Receipt of ≥ 100 mL/kg/year of pRBC per year • Must have a Karnofsky performance status of ≥ 80% for subjects ≥ 16 years of age or a Lansky performance status of ≥ 80% for subjects < 16 years of age • Patient must be eligible to undergo hematopoietic stem cell transplant (HSCT) • Enrollee has been assessed for an HLA-matched sibling donor Hematopoietic Stem Cell Transplant (HSCT) and determined not to be a candidate based on match • Physician attests that enrollee is fit to receive Casgevy therapy, including therapy for myeloablative conditioning • Patient has been screened and found negative for active infections of the following: hepatitis B virus (HBV), hepatitis C virus (HCV), and human immunodeficiency virus 1 & 2 (HIV-1/HIV-2) in accordance with clinical guidelines prior to collection of cells (documentation of laboratory results taken within the past 3 months is required) • Enrollee will not receive concomitant therapy with any of the following: o Iron chelators for 7-days prior to mobilization and 6 months post-treatment (3-months post-treatment for non-myelosuppressive iron chelators) AND o Disease-modifying agents (e.g., voxelotor, crizanlizumab, L- glutamine) for at least 8-weeks prior to mobilization AND o Hydroxyurea for at least 2 months prior to mobilization	• See FDA Prescribing Information
Exclusion Criteria		
Sickle Cell Disease Therapy will not be approved if any of the below criteria are met: • An accessible and willing 10/10 human leukocyte antigen (HLA)-matched related donor • Prior receipt of allogeneic or autologous HSCT • Prior treatment with gene therapy/editing product		

- Clinically significant and active bacterial, viral, fungal, or parasitic infection
- History of untreated Moyamoya disease or presence of Moyamoya disease
- Advanced liver disease, defined as any of the following:
    - Alanine transaminase (ALT) > 3 × the upper limit of normal (ULN) or direct bilirubin value > 2.5 × ULN
    - Baseline prothrombin time (PT) (international normalized ratio [INR]) > 1.5 × ULN
    - History of cirrhosis or any evidence of bridging fibrosis, or active hepatitis
- Baseline estimated glomerular filtration rate < 60 mL/min/1.73 m2 (documentation of laboratory results taken within the past 3 months is required)
- Any contraindications to the use of plerixafor during the mobilization of hematopoietic stem cells and any contraindications to the use of busulfan and any other medicinal products required during the myeloablative conditioning, including hypersensitivity to the active substances or to any of the excipients.
- Any prior or current malignancy or myeloproliferative disorder or a significant immunodeficiency disorder.
- History of familial cancer syndrome

Transfusion-dependent β-Thalassemia
Therapy will not be approved if any of the below criteria are met:

- An accessible and willing 10/10 human leukocyte antigen (HLA)-matched related donor
- Prior receipt of allogeneic or autologous HSCT
- Prior treatment with gene therapy/editing product
- Significant and active bacterial, viral, fungal, or parasitic infection
- α-thalassemia and > 1 alpha chain deletion, or alpha multiplications
- White blood cell (WBC) count < 3×10^9/L or platelet count < 50×10^9/L not related to hypersplenism (documentation of laboratory results taken within the past 3 months is required)
    - NOTE: If patient has a white blood cell count less than $3 \text{ X } 10^9$/L, and/or platelet count less than $100 \text{ X } 10^9$/L, then documentation of hypersplenism (i.e., ultrasound) is required
- Any prior or current malignancy or myeloproliferative disorder or a significant immunodeficiency disorder
- A cardiac T2* < 10 ms by MRI or left ventricular ejection fraction (LVEF) < 45% by echocardiogram
- Baseline estimated glomerular filtration rate < 60 mL/min/1.73 m2 (documentation of laboratory results taken within the past 3 months is required)
- Any contraindications to the use of plerixafor or granulocyte colony stimulating factor (G-CSF) during the mobilization of hematopoietic stem cells and any contraindications to the use of busulfan and any other medicinal products required during the myeloablative conditioning, including hypersensitivity to the active substances or to any of the excipients.
- Advanced liver disease, defined as any of the following:
    - Aspartate transaminase (AST), alanine transaminase (ALT) > 3 x the upper limit of normal (ULN), or direct bilirubin value > 2.5 x the ULN
    - Baseline prothrombin time (International Normalized Ratio; INR) > 1.5 x ULN
    - History of cirrhosis or any evidence of bridging fibrosis, or active hepatitis on previous liver biopsy.
    - Liver iron content (LIC) ≥ 15 mg/g on R2* MRI of liver

Continuation Criteria

- Not applicable
- If approved, therapy will only be approved for one lifetime administration

Considerations

- Prior authorization is obtained through the CDPHP pharmacy department
- Casgevy (exagamglogene autotemcel) is considered not medically necessary when the above criteria are not met.
- Casgevy (exagamglogene autotemcel) is considered not medically necessary for all other indications.
- Physician acknowledges that CDPHP will request documentation, not more frequently than biannually, of follow-up patient assessments including but not limited to:
    - Sickle Cell disease: occurrence of VOE's/VOC's, laboratory findings, and other hematologic clinical events

- Transfusion-dependent β-Thalassemia: occurrence of RBC transfusion events, laboratory findings, and other hematologic clinical events

GOVERNMENT PROGRAMS

CHILD HEALTH PLUS: Subject to all terms and conditions noted in above application.

MEDICARE CHOICES: Subject to all terms and conditions noted in above application.

SELECT/HARP PLAN: Effective January 1st, 2026, Casgevy and Lyfgenia will be reimbursed by the NYS Medicaid fee-for-service (FFS) program for Managed Medicaid/HARP members. The prior authorization process for these medications will remain unchanged. The Plan will continue to review these medications for medical necessity.

CDPHP Pharmacy Services 7/14/2026

New: 12/2023

Revised	Reviewed
2/2024, 2/2026, 5/2026, 7/2026	2/2025

Revision Date	Changes Made
2/2024	Changed title to include FDA Brand Name (Casgevy) Added FDA approved indication of Transfusion-dependent Beta-thalassemia, including Inclusion and Exclusion Criteria
12/2025	Updated authorization duration to 6 months to allow adequate time for administration Updated age range from 12-35 to at least 12 years of age Added Karnofsky performance status or Lansky performance status Added not receiving concomitant therapy Updated language regarding Medicaid applicability Updated exclusion criteria
2/2026	Clarified genetic variants of beta thalassemia
5/2026	Removed criteria for being followed for 24 months at certified center Updated genotypes for sickle cell disease Removed baseline hemoglobin and physician attestation of fitness for β-thalassemia Added HCPCS Code
7/2026	Added must be screened and negative for Hep B, C, and HIV Updated age

PROCEDURE CODES

Other Licensed Practitioner (OLP): 90791, H0004, H2011, 90882
Community Psychiatric Support and Treatment (CPST): H0036
Psychosocial Rehabilitation (PSR): H2017
Family Peer Support Services (FPSS): H0038
Youth Peer Support and Training (YPSS): H0038
Crisis Intervention (CI), including Crisis Residential Services: H2011, S9484, S9485,

DESCRIPTION

Children and Family Treatment and Support Services (CFTSS) consist of services for children (under 21 years of age) include the following:

Other Licensed Practitioner (OLP)
Services provided by a non-physician behavioral health practitioner (NP-LBHP) in the community in order to effectively engage children and youth.

Activities include:

- Recommending treatment that also considers trauma-informed, cultural variables and nuances,
- Individual, family, and/or group outpatient psychotherapy and behavioral health assessment, evaluation, and testing consistent with the American Medical Association (AMA) definitions of the covered Current Procedural Terminology (CPT) codes and other activities within the scope of all applicable state laws and their professional license.

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: CHILDREN AND FAMILY TREATMENT AND SUPPORT SERVICES (CFTSS)

Crisis Intervention (CI)
Services provided to a member identified as experiencing an acute psychological/emotional change which results in a marked increase in personal distress and which exceeds the abilities and the resources of those involved (e.g. collateral, provider, community member) to effectively resolve it.

Crisis Intervention services are provided to the member who is experiencing a psychiatric or substance use crisis, and his/her family/caregiver, and are designed to:
- Interrupt and/or ameliorate the crisis experience
- Include an assessment that is culturally and linguistically sensitive
- Result in immediate crisis resolution and de-escalation

Community Psychiatric Support and Treatment (CPST)
Goal-directed supports and solution-focused interventions intended to address challenges associated with a behavioral health need and to achieve identified goals or objectives as set forth in the enrollee's treatment plan.

Designed to provide community-based services to children and families who may have difficulty engaging in formal office settings, but can benefit from community based rehabilitation services.

Services may include one or more of the following:
- Rehabilitative psychoeducation
- Intensive interventions
- Strength based treatment planning
- Rehabilitative supports
- Crisis avoidance
- Intermediate term crisis management

Psychosocial Rehabilitation (PSR)
Services designed to work with children and their families to implement interventions outlined in a treatment plan to compensate for or eliminate functional deficits and interpersonal and/or environmental barriers associated with a child/youth's behavioral health needs.

Family Peer Support Services (FPSS)
Formal and informal activities and supports provided to families caring for/raising a child/youth who is experiencing social, emotional, medical, developmental, substance use, and/or behavioral challenges in their home, school, placement, and/or community. Services provide a structured, strength-based relationship between a family peer advocate (FPA) and the parent/family member/caregiver for the benefit if the child/youth.

Youth Peer Support and Training (YPST)
Formal and informal services and supports provided to youth, who are experiencing social, emotional, medical, developmental, substance use, and/or behavioral challenges in their home, school, placement, and/or community. Services provide the training and support necessary to ensure engagement and active participation of the youth in the treatment planning process and with the ongoing implementation and reinforcement of skills.

N/A

POSITION STATEMENT

CDPHP does not provide coverage for the ambulatory mental health programs identified above except for Select Plan as described below.

POLICY CONSIDERATIONS

FOR SELECT PLAN AND CHILD HEALTH PLUS

Benefits are provided for the following ambulatory mental health programs for an enrollee under 21 years of age unless otherwise specified when criteria outlined below are met.

Other Licensed Practitioner (OLP)
Note: Benefits for Non-SSI children are effective 1/1/19. Benefits for SSI children are effective 7/1/19. Benefits for Child Health Plus children are effective 1/1/23.

OLP does not require a DSM diagnosis in order for services to be delivered.

Service is delivered by a non-physician licensed behavioral health practitioner (NP-LBHP) who is licensed in New York state, operating within the scope of practice defined in state law and in any setting permissible under state law practice. NP-LBHP include:

- Licensed psychoanalyst
- Licensed clinical social worker (LCSW)
- Licensed marriage and family therapist
- Licensed mental health counselor
- Licensed master social worker under the supervision/direction of a LCSW, licensed psychologist, or psychiatrist.

Practitioner must operate within a child-serving agency that is licensed, certified, designated and/or approved by New York State OCFS, OMH, OASAS or DOH, or its designee, in setting permissible by that designation.

Treatment services must be part of a treatment plan including goals and activities necessary to correct or ameliorate conditions discovered during the initial assessment.

Medically necessary services that are best delivered in a school setting by a community provider need to be detailed in the treatment plan.

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: CHILDREN AND FAMILY TREATMENT AND SUPPORT SERVICES (CFTSS)

Admission Criteria
One of the following criteria is met:

- Treatment to correct or ameliorate condition(s) found through an early and periodic screening, diagnostic and treatment (EPSDT) screening; *or*
- Treatment addressing the prevention, diagnosis, and/or treatment of health impairments; the ability to achieve age-appropriate growth and development, and the ability to attain, maintain, or regain functional capacity.

Continued Stay Criteria

- Enrollee is making some progress, but has not fully achieved established service goals and there is an expectation that if the enrollee continues, there will be improvement; *or*
- All of the following:
  - Continuation of service is needed to prevent the loss of functional skills already achieved;
  - Continues to meet admission criteria;
  - Enrollee and/or family/caregiver(s) continue to be engaged in services;
  - Alternative service(s) would not meet enrollee's needs;
  - Treatment plan has been updated to establish or modify ongoing goals.

Discharge Criteria
Meets one of the following:

- Enrollee no longer meets continued stay criteria; *or*
- Enrollee has successfully reached individual/family established service goals for discharge; *or*
- Enrollee or parent/caregiver(s) withdraws consent for services; *or*
- Enrollee is not making progress on established service goals, nor is there expectation of any progress with continued provision of services; *or*
- Enrollee is no longer engaged in the service, despite multiple attempts on the part of the provider to apply reasonable engagement strategies; *or*
- Enrollee and/or family/caregiver(s) no longer needs service as s/he is obtaining a similar benefit through other services and resources.

Limits/Exclusions

- Educationally necessary services provided by a school employee must be included in the individualized education plan (IEP) and are not reimbursed by CDPHP or Medicaid fee for service (FFS).
- Services rendered while a resident of an institution for mental disease are part of the institutional service and not otherwise reimbursable.
- Visits to intermediate care facilities for enrollee with mental retardation are not covered.
- Visits to nursing facilities are allowed for licensed professionals other than social workers if a preadmission screening and resident review (PASRR) indicates it is medically necessary treatment. Social worker visits are included in the nursing facility visit and may not be billed separately.

Crisis Intervention
Note: Benefits effective 1/1/20. Crisis Residential Services effective 12/1/20. Benefits for Child Health

CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: CHILDREN AND FAMILY TREATMENT AND SUPPORT SERVICES (CFTSS)

Plus children are effective 1/1/23.

Crisis services cannot be denied based upon substance use.

Admission Criteria
All of the following criteria are met:

- Experiencing acute psychological/emotional change which results in a marked increase in personal distress and which exceeds the abilities and the resources of those involved (e.g. collateral, provider, community member) to effectively resolve it; *and*
- Demonstrates at least one of the following:
- Suicidal/assaultive/destructive ideas, threats, plans or actions that represent a risk to self or others; *or*
- Impairment in mood/thought/behavior disruptive to home. School, or the community; *or*
- Behavior escalating to the extent that a higher intensity of services will likely be required *and*
- Intervention is necessary to further evaluate, resolve, and/or stabilize to previous level of functioning; *and*
- Service is recommended by any of the following licensed practitioners of the healing arts operating within the scope of their practice of their state license:
  - Psychiatrist
  - Physician
  - Licensed psychoanalyst
  - Registered professional nurse
  - Nurse practitioner
  - Clinical nurse specialist
  - Licensed clinical social worker (LCSW)
  - Licensed marriage and family therapist
  - Licensed mental health counselor
  - Licensed psychologist

Discharge Criteria
Meets one of the following:

- No longer meets admission criteria (demonstrates symptom reduction, stabilization, and restoration, or developing the coping mechanisms to pre-crisis levels of functioning) and/or meets criteria for another level of care, either more or less intensive; *or*
- Enrollee or parent/caregiver(s) withdraw consent for services.

Limitations/Exclusions

- The following activities are excluded:
  - Financial management
  - Supportive housing
  - Supportive employment services
  - Basic skills acquisition services that are habilitative in nature
- Services may not be primarily educational, vocational, recreational, or custodial (i.e., for the purpose of assisting with the activities of daily living; for maintaining the enrollee's or anyone else's safety; and could be provided by persons without professional skills/training)
- Does not include services, supplies or procedures performed in a non-conventional setting including:

resorts, spas, therapeutic programs, and camps.

Crisis Residential Services for Children

- Services provided at Crisis Residence programs are one component of a comprehensive continuum of crisis services, intended to help avert extended emergency room visits and inpatient hospitalizations.
- Children must be in crisis or at risk of being in crisis (psychiatric distress) to be admitted
- For admission to a Children's Crisis Residence, a mental health diagnosis is not required
- Children cannot be at imminent risk of self-harm or harm to others
- There are three Crisis Residence Programs available to youth under 21 years of age:
  - Children's Crisis Residences – available to youth up to age 21
  - Intensive Crisis Residence Programs and Residential Crisis Support Programs (see Ambulatory Mental Health Programs, 1370/20.000488 for more information) – available for youth ages 18 and older

- Service components for Children's Crisis Residence include:
  - Comprehensive Intake Assessment including:
    - Mental Health assessment
    - Risk assessment and crisis planning
    - Health screening for physical conditions
  - Service Planning
  - Care Coordination
  - Individual and family counseling including:
    - Alleviating psychiatric symptoms, maintaining stabilization and preventing escalation of mental health symptoms including providing a relief or break for the child/youth
    - Consulting with psychiatric prescribers and urgent psychopharmacology intervention including medication monitoring and medication management and training, as needed
    - Resolving conflict, de-escalating and monitoring of high-risk behavior, including providing one-to-one monitoring and behavior supports
    - Family Support

Community Psychiatric Support and Treatment (CPST)

Note: Benefits for Non-SSI children are effective 1/1/19. Benefits for SSI children are effective 7/1/19. Benefits for Child Health Plus children are effective 1/1/23.

Service components include:

- Rehabilitative psychoeducation
- Intensive interventions
- Strengths based treatment planning
- Rehabilitative supports
- Crisis avoidance
- Intermediate term crisis management

Treatment services must be part of the treatment plan including goals and activities necessary to correct or ameliorate conditions covered during the initial assessment visits.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: CHILDREN AND FAMILY TREATMENT AND SUPPORT SERVICES (CFTSS)

Admission Criteria

All of the following criteria are met:

- Enrollee has a behavioral health diagnosis that demonstrates symptoms consistent or corresponding with the DMS; *or* is at risk of development of a behavioral health diagnosis; *and*
- Enrollee is expected to achieve skill restoration in one of the following areas:
  - Participation in community activities and/or positive peer support networks;
  - Personal relationships;
  - Personal safety and/or self-regulation;
  - Independences/productivity;
  - Daily living skills;
  - Symptom management;
  - Copies strategies and effective functioning in the home, school, social or work environment; *and*
- Enrollee is likely to benefit from and respond to the service to prevent the onset or worsening of symptoms; *and*
- Service is recommended by any of the following licensed practitioners of the healing arts operating within the scope of their practice of their state license:
  - Licensed master social worker
  - Licensed clinical social worker
  - Licensed mental health counselor
  - Licensed creative arts therapist
  - Licensed marriage and family therapist
  - Licensed psychoanalyst
  - Physician assistant
  - Psychiatrist
  - Physician
  - Registered professional nurse
  - Nurse practitioner

Continued Stay Criteria

All of the following criteria are met:

- Enrollee continues to meet admission criteria; *and*
- Enrollee shows evidence of engagement toward resolution of symptoms but has not fully reached established service plan goals and there is an expectation that if the service continues, the enrollee will continue to improve; *and*
- Enrollee does not require an alternate and/or higher, more intensive level of care or treatment; *and*
- Enrollee is at risk of losing skills gain if the service is not continued; *and*
- Treatment planning includes family/caregiver(s) and/or other support systems, unless not clinically indicated or relevant.

Discharge Criteria

Meets one of the following:

- Enrollee no longer meets admission criteria and/or meets criteria for another level of care, either more or less intensive; *or*
- Enrollee has successfully met the specific goals outlined in the treatment plan for discharge; *or*
- Enrollee or parent/caregiver(s) withdraws consent for services; *or*

- Enrollee is not making progress on established service goals, nor is there expectation of any progress with continued provision of services; *or*
- Enrollee is no longer engaged in the service, despite multiple attempts by the provider to apply reasonable engagement strategies; *or*
- Enrollee and/or family/caregiver(s) no longer needs service as s/he is obtaining a similar benefit through other services and resources.

Limitations/Exclusions

- Enrollee with a developmental disability diagnosis without a co-occurring behavioral health condition is not eligible for this service.

Psychosocial Rehabilitation (PSR)

Note: Benefits for Non-SSI children are effective 1/1/19. Benefits for SSI children are effective 7/1/19. Benefits for Child Health Plus children are effective 1/1/23.

Treatment services must be a part of a treatment plan including goals and activities necessary to correct or ameliorate conditions discovered during the initial assessment visit

Admission Criteria

All of the following criteria are met:

- Enrollee has a behavioral health diagnosis that demonstrates symptoms consistent or corresponding with the DMS; *and*
- Enrollee is likely to benefit from and respond to the service to prevent the onset or the worsening of symptoms; *and*
- Service is needed to meet rehabilitative goals by restoring, rehabilitating, and/or supporting enrollee's functional level to facilitate integration of the enrollee as participant of his/her community and family; *and*
- Service is recommended by any of the following licensed practitioners of the healing arts operating within the scope of their practice of their state license:
  - Licensed master social worker
  - Licensed clinical social worker
  - Licensed mental health counselor
  - Licensed creative arts therapist
  - Licensed marriage and family therapist
  - Licensed psychoanalyst
  - Licensed psychologist
  - Physician assistant
  - Psychiatrist
  - Physician
  - Registered professional nurse
  - Nurse practitioner

Continued Stay Criteria

All of the following criteria are met:

- Enrollee continues to meet admission criteria; *and*

- Enrollee shows evidence of engagement toward resolution of symptoms but has not fully reached established service plan goals and there is an expectation that if the service continues, the enrollee will continue to improve; *and*
- Enrollee does not require an alternate and/or higher, more intensive level of care or treatment; *and*
- Enrollee is at risk of losing skills gain if the service is not continued; *and*
- Treatment planning includes family/caregiver(s) and/or other support systems, unless not clinically indicated or relevant.

Discharge Criteria
Meets one of the following:
- Enrollee no longer meets admission criteria and/or meets criteria for another level of care, either more or less intensive; *or*
- Enrollee has successfully met the specific goals outlined in the treatment plan for discharge; *or*
- Enrollee or parent/caregiver(s) withdraws consent for services; *or*
- Enrollee is not making progress on established service goals, nor is there expectation of any progress with continued provision of services; *or*
- Enrollee is no longer engaged in the service, despite multiple attempts on the part of the provider to apply reasonable engagement strategies; *or*
- Enrollee and/or family/caregiver(s) no longer needs service as s/he is obtaining a similar benefit through other services and resources.

Limitations/Exclusions
- Enrollee with a developmental disability diagnosis without a co-occurring behavioral health condition is not eligible for this service

Family Peer Support Services (FPSS)
Note: Benefits effective 7/1/19. Benefits for Child Health Plus children are effective 1/1/23.

Treatment services must be part of the treatment plan including goals and activities necessary to correct or ameliorate conditions covered during the initial assessment visits.

Admission Criteria
All of the following criteria are met:
- Enrollee has a behavioral health diagnosis that demonstrates symptoms consistent or corresponding with the DMS; *or* displays demonstrated evidence of skill(s) lost or undeveloped as a result of the impact of his/her physical health diagnosis; *and*
- Enrollee is likely to benefit from and respond to the service to prevent the onset or the worsening of symptoms; *and*
- Enrollee's family is available, receptive to and demonstrates need for improvement in the following areas such as, but not limited to:
  - Strengthening the family unit
  - Building skills within the family for the benefit of the enrollee
  - Promoting empowerment within the family
  - Strengthening overall supports in the enrollee's environment

  and

POLICY NAME: CHILDREN AND FAMILY TREATMENT AND SUPPORT SERVICES (CFTSS)

- Service is recommended by any of the following licensed practitioners of the healing arts operating within the scope of their practice of their State license:
  - Licensed master social worker
  - Licensed clinical social worker
  - Licensed mental health counselor
  - Licensed creative arts therapist
  - Licensed marriage and family therapist
  - Licensed psychoanalyst
  - Licensed psychologist
  - Physician assistant
  - Psychiatrist
  - Physician
  - Registered professional nurse
  - Nurse practitioner

Continued Stay Criteria

All of the following criteria are met:

- Enrollee continues to meet admission criteria; *and*
- Enrollee is making progress but has not fully reached established service goals and there is a reasonable expectation that continued services will increase the enrollee meeting service goals; *and*
- Family/caregiver(s) participation in treatment is adequate to meaningfully contribute to the enrollee's progress in achieving service goals; *and*
- Additional psychoeducation or training to assist the family/caregiver understanding the enrollee's progress and treatment or to care for the enrollee would contribute to the enrollee's progress; *and*
- Enrollee does not require an alternate and/or higher, more intensive level of care or treatment; *and*
- Enrollee is at risk of losing skills gain if the service is not continued; *and*
- Treatment planning includes family/caregiver(s) and/or other support systems, unless not clinically indicated or relevant.

Discharge Criteria

Meets one of the following:

- Enrollee and/or family/caregiver no longer meets admission criteria; *or*
- Enrollee has successfully met the specific goals outlined in the treatment plan for discharge; *or*
- Family withdraws consent for services; *or*
- Enrollee and/or family is not making progress on established service goals, nor is there expectation of any progress with continued provision of services; *or*
- Enrollee and/or family is no longer engaged in the service, despite multiple attempts on the part of the provider to apply reasonable engagement strategies; *or*
- Family/caregiver(s) no longer needs service as s/he is obtaining a similar benefit through other services and resources.

Limitations/Exclusions

- Enrollee with a developmental disability diagnosis without a co-occurring behavioral health condition is not eligible for this service

- The following activities are excluded from FPSS:
  - 12-step programs run by peers.
  - General outreach and education including participation in health fairs, and other activities designed to increase the number of individuals served or the number of services received by individuals accessing services; community education services, such as health presentations to community groups, PTAs, etc.
  - Contacts that are not medically necessary.
  - Time spent doing, attending, or participating in recreational activities.
  - Services provided to teach academic subjects or as a substitute for educational personnel such as, but not limited to, a teacher, teacher's aide, or an academic tutor.
  - Time spent attending school (e.g., during a day treatment program).
  - Habilitative services for the child/youth to acquire self-help, socialization, and adaptive skills necessary to reside successfully in community setting.
  - Childcare services or services provided as a substitute for the parent or other individuals responsible for providing care and supervision.
  - Respite care.
  - Transportation for the enrollee or family. Services provided in the car are considered transportation and time may not be billed under rehabilitation.
  - Services not identified on the enrollee's authorized treatment plan.
  - Services not in compliance with the service manual and not in compliance with State Medicaid standards.
  - Services provided to children, spouse, parents, or siblings of the enrollee under treatment or others in the enrollee's life to address problems not directly related to the enrollee's issues and not listed on the enrollee's treatment plan.
  - Any intervention or contact not documented or consistent with the approved treatment/recovery plan goals, objectives, and approved services will not be reimbursed.

Youth Peer Support and Training
Note: Benefits effective 1/1/20. Benefits for Child Health Plus children are effective 1/1/23.

Treatment services must be part of the treatment plan including goals and activities necessary to correct or ameliorate conditions covered during the initial assessment visits.

Admission Criteria
All of the following criteria are met:
- Enrollee has a behavioral health diagnosis that demonstrates symptoms consistent or corresponding with the DMS; *or* displays demonstrated evidence of skill(s) lost or undeveloped as a result of the impact of his/her physical health diagnosis; *and*
- Enrollee requires involvement of a youth peer advocate to implement the intervention(s) outlined in the treatment plan; *and*
- Enrollee demonstrates a need for improvement in the following areas such as, but not limited to:
  - Enhancing enrollee's ability to effectively manage comprehensive health needs
  - Maintaining recovery
  - Strengthening resiliency, self-advocacy
  - Self-efficacy and empowerment

  - Developing competency to utilize resources and supports in the community
  - Transition into adulthood or participate in treatment

  and
- Enrollee is involved in the admission process and helps determine service goals; *and*
- Enrollee is available and receptive to receiving this service; *and*
- Service is recommended by any of the following licensed practitioners of the healing arts operating within the scope of their practice of their state license:
  - Licensed master social worker
  - Licensed clinical social worker
  - Licensed mental health counselor
  - Licensed creative arts therapist
  - Licensed marriage and family therapist
  - Licensed psychoanalyst
  - Licensed psychologist
  - Physician assistant
  - Psychiatrist
  - Physician
  - Registered professional nurse
  - Nurse practitioner

Continued Stay Criteria

All of the following criteria are met:
- Enrollee continues to meet admission criteria; *and*
- Enrollee shows evidence of engagement toward resolution of symptoms but has not fully reached established service goals and there is expectation that if the service continues, the enrollee will continue to improve; *and*
- Enrollee does not require an alternate and/or higher, more intensive level of care or treatment; *and*
- Enrollee is at risk of losing skills gain if the service is not continued; *and*
- Treatment planning includes family/caregiver(s) and/or other support systems, unless not clinically indicated.

Discharge Criteria

Meets one of the following:
- Enrollee and/or family/caregiver no longer meets admission criteria; *or*
- Enrollee has successfully met the specific goals outlined in the treatment plan for discharge; *or*
- Enrollee or parent/caregiver withdraws consent for services; *or*
- Enrollee is not making progress on established service goals, nor is there expectation of any progress with continued provision of services; *or*
- Enrollee is no longer engaged in the service, despite multiple attempts on the part of the provider to apply reasonable engagement strategies; *or*
- Enrollee no longer needs service as s/he is obtaining a similar benefit through other services and resources.

Limitations/Exclusions

- Enrollee with a developmental disability diagnosis without a co-occurring behavioral health condition

is not eligible for this service.

- The following activities are excluded from YPSS:
  - 12-step programs run by peers.
  - General outreach and education including participation in health fairs, and other activities designed to increase the number of individuals served or the number of services received by individuals accessing services; community education services, such as health presentations to community groups, PTAs, etc.
  - Contacts that are not medically necessary.
  - Time spent doing, attending, or participating in recreational activities.
  - Services provided to teach academic subjects or as a substitute for educational personnel such as, but not limited to, a teacher, teacher's aide, or an academic tutor.
  - Time spent attending school (e.g., during a day treatment program).
  - Habilitative services for the child/youth to acquire self-help, socialization, and adaptive skills necessary to reside successfully in community setting.
  - Childcare services or services provided as a substitute for the parent or other individuals responsible for providing care and supervision.
  - Respite care.
  - Transportation for the enrollee or family. Services provided in the car are considered transportation and time may not be billed under rehabilitation.
  - Services not identified on the enrollee's authorized treatment plan.
  - Services not in compliance with the service manual and not in compliance with State Medicaid standards.
  - Services provided to children, spouse, parents, or siblings of the enrollee under treatment or others in the enrollee's life to address problems not directly related to the enrollee's issues and not listed on the enrollee's treatment plan.
  - Any intervention or contact not documented or consistent with the approved treatment/recovery plan goals, objectives, and approved services will not be reimbursed.

Considerations for Telehealth

- Every OMH-designated CFTSS provider must obtain OMH approval pursuant to Part 596 to provide Telehealth Services.
- CFTSS are designed to be delivered in the natural environment, specifically the home and community-based settings. Therefore, providers should prioritize in-person service delivery.
- Telehealth must not replace in-person program requirements.
- Telehealth may be used to supplement in-person services, to optimize engagement (e.g., for screening so that the individual can learn about choices in services), to temporarily provide care in circumstances where in-person engagement is not possible (e.g., risk of infection), or to engage others in the individual's care, such as for family therapy sessions, collateral contacts, etc.
- Where services are provided using telehealth, audio-visual modalities are strongly encouraged, unless an individual does not have access to audio-visual technology (in which case, provider should assist individual in obtaining audio-visual technology, or training or otherwise helping them become comfortable using audio-visual technology).
- See NYS OMH April 2023 Telehealth Services Guidance for OMH Providers

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: CHILDREN AND FAMILY TREATMENT AND SUPPORT SERVICES (CFTSS)

EXCLUSIONS

Rehabilitative services do not include the following:

- Educational, vocational and job training services
- Room and board
- Habilitation services
- Services to inmates in public institutions as defined by 42 CFR 435.1010
- Recreational and social activities
- Services that must be covered elsewhere in the state Medicaid plan

Audio-only telehealth services to conduct Other Licensed Practitioner (OLP) evaluations for children/youth for the sole purpose of informing eligibility for alternative programming is excluded from coverage

OLP Crisis Off-site is restricted to in-person services only, and cannot be delivered via telehealth

CDPHP PRODUCT VARIATIONS

CHILD HEALTH PLUS:	Subject to all terms and conditions noted above in the policy, effective 1/1/23.
MEDICARE ADVANTAGE:	Medicare does not provide coverage for the ambulatory mental health supports identified above.
SELECT PLAN/HARP:	HARP does not provide coverage for the ambulatory mental health supports identified above.

POLICY HISTORY

This section is intended to provide only highlights of the policy changes. The policy should always be reviewed in its entirety to ensure a comprehensive understanding of coverage.

Effective Date	Update
8/1/2023	Updated Policy Name from "Ambulatory Mental Health Programs for Children" to "Children and Family Treatment and Support Services". Removed H2013 from Crisis Intervention Services (Crisis Residential Services removed from CFTSS, and is standalone OMH SPA benefit). Added Considerations for Telehealth section. Updated Source documents.
1/1/2023	Benefit added for CHP plans.
12/1/2020	Addition of Crisis Residential Services description, coverage criteria, and code H2013.
1/1/2020	Reference to age limit of 14-21 as being criteria for coverage for programs is removed. As of 1/1/20, NYS is prohibiting plans from conducting utilization review on mental health services for individuals under age 21.

This Resource Coordination Policy is the exclusive property of Capital District Physicians' Health Plan, Inc. (CDPHP®) and its affiliated companies, CDPHP Universal Benefits,® Inc. (CDPHP UBI) and Capital District Physicians' Healthcare Network, Inc. (CDPHN). The contents and form of this policy are proprietary to CDPHP. Any reproduction or replication of this policy without the express written permission of CDPHP, CDPHP UBI, and CDPHN is strictly prohibited. This policy is subject to contractual limitations and/or parameters established in any Employer sponsored Summary Plan Description (SPD) and/or Benefit Design Document (BDD).

Policy/Procedure Name: Chimeric Antigen Receptor T-Cell (CAR-T) Therapy **Control Number:** 1350/20.000503

Disclaimer Notice

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgment when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

Background

The spontaneous regression of certain cancers (e.g., renal cell carcinoma and melanoma) supports the idea that a patient's immune system can delay tumor progression and, on infrequent occasions, can eliminate tumors altogether. These observations have led to research into various immunologic therapies designed to stimulate a patient's own immune system.

Engineered T-cell–based antitumor immunotherapy uses gene transfer of tumor antigen-specific T-cell receptors (TCR) or synthetic chimeric antigen receptors (CAR-T). CAR-T cells are prepared from the patient's peripheral blood mononuclear cells, which are obtained via a standard leukapheresis procedure. The blood is sent to the manufacturer where the mononuclear cells are enriched for T-cells. The T-cells are expanded in cell culture, washed, and formulated into a suspension, which then is cryopreserved. This process may take several weeks. The product is then infused into the patient. This technique has shown very encouraging results in clinical trials for treatment of types of leukemias and lymphomas. However, CAR-T cells can persist more than six years in patients and can lead to severe adverse events shortly after infusion as well as at later times.

Cytokine-release syndrome (CRS) and other toxicities pose significant risks for patients. Providers should develop toxicity management plans for patients undergoing CAR-T therapy.

In November 2023 the FDA released a statement regarding the possible increased risk of T-cell malignancies following treatment with CAR-T therapy, after receiving reports from clinical trials and/or post marketing adverse event data sources. The release stated that "Although the overall benefits of these products continue to outweigh their potential risks for their approved uses, FDA is investigating the identified risk of T-cell malignancy with serious outcomes, including hospitalization and death, and is evaluating the need for regulatory action." It also advised that "Patients and clinical trial participants receiving treatment with these products should be monitored life-long for new malignancies. In the event that a new malignancy occurs following treatment with these products, contact the manufacturer to report the event and obtain instructions on collection of patient samples for testing for the presence of the Chimeric Antigen Receptor (CAR) transgene."

There are seven FDA-approved CAR-T therapies as of December 2024, some of which were approved under the accelerated approval based on response rate and durability of response. Continued approval for these indications may be contingent upon verification and description of clinical benefit in a confirmatory trial(s). These indications are designated in the chart below with an asterisk.

On June 26, 2025, the FDA removed the REMS program requirements from the CAR-T products.

FDA-approved approved CAR-T therapies indications include:

Trade name	Year Approved	Mechanism	Indication(s)
Abecma® (idecabtagene vicleucel) Q2055	2021	B-cell maturation antigen (BCMA)-directed genetically modified autologous T-cell immunotherapy	Adult patients with relapsed or refractory multiple myeloma after four or more prior lines of therapy, including an immunomodulatory agent, a proteasome inhibitor, and an anti-CD38 monoclonal antibody.
Aucatzyl® (obecabtagene autoleucel) Q2058	2024	CD19-directed genetically modified autologous T-cell immunotherapy	Adult patients with relapsed or refractory B-cell precursor acute lymphoblastic leukemia (ALL).
Breyanzi® (lisocabtagene maraleucel) Q2054	2021	CD19-directed genetically modified autologous T-cell immunotherapy	Adult patients with large B-cell lymphoma (LBCL), including diffuse large B-cell lymphoma (DLBCL) not otherwise specified (including DLBCL arising from indolent lymphoma), high-grade B-cell lymphoma, primary mediastinal large B-cell lymphoma, and follicular lymphoma grade 3B, who have:

			• Refractory disease to first-line chemoimmunotherapy or relapse within 12 months of first-line chemoimmunotherapy or • Refractory disease to first-line chemoimmunotherapy or relapse after first line chemoimmunotherapy and are not eligible for hematopoietic stem cell transplantation (HSCT) due to comorbidities or age or • Relapsed or refractory disease after two or more lines of systemic therapy Adult patients with relapsed or refractory chronic lymphocytic leukemia (CLL) or small lymphocytic lymphoma (SLL) who have received at least 2 prior lines of therapy, including a Bruton tyrosine kinase (BTK) inhibitor and a B-cell lymphoma 2 (BCL-2) inhibitor.* Adult patients with relapsed or refractory follicular lymphoma (FL) who have received 2 or more prior lines of systemic therapy.* Adult patients with relapsed or refractory mantle cell lymphoma (MCL) who have received at least 2 prior lines of systemic therapy, including a Bruton tyrosine kinase (BTK) inhibitor.* Adult patients with relapsed or refractory marginal zone lymphoma (MZL) who have received at least 2 prior lines of systemic therapy.
Carvykti® (ciltacabtagene autoleucel) Q2056	2022	B-cell maturation antigen (BCMA)-directed genetically modified autologous T-cell immunotherapy	Adult patients with relapsed or refractory multiple myeloma who have received at least 1 prior line of therapy, including a proteasome inhibitor and an immunomodulatory agent, and are refractory to lenalidomide.
Kymriah® (tisagenlecleucel) Q2042	2017	CD19-directed genetically modified autologous T-cell immunotherapy	Treatment of: • Patients up to 25 years of age with B-cell precursor acute lymphoblastic leukemia (ALL) that is refractory or in second or later relapse. • Adult patients with relapsed or refractory large B-cell lymphoma after two or more lines of systemic therapy, including diffuse large B-cell lymphoma (DLBCL) not otherwise specified, high grade B-cell lymphoma and DLBCL arising from follicular lymphoma. (Not indicated for treatment of patients with primary central nervous system lymphoma). • Adult patients with relapsed or refractory follicular lymphoma (FL) after two or more lines of systemic therapy.*
Tecartus® (brexucabtagene autoleucel) Q2053	2020	CD19-directed genetically modified autologous T-cell immunotherapy	• Adult patients with relapsed or refractory mantle cell lymphoma (MCL).* • Adult patients with relapsed or refractory B-cell precursor acute lymphoblastic leukemia (ALL).
Yescarta® (axicabtagene ciloleucel) Q2041	2017	CD19-directed genetically modified autologous T-cell immunotherapy	• Adult patients with large B-cell lymphoma that is refractory to first-line chemoimmunotherapy or that relapses within 12 months of first-line chemoimmunotherapy. • Adult patients with relapsed or refractory large B-cell

			lymphoma after two or more lines of systemic therapy, including diffuse large B-cell lymphoma (DLBCL) not otherwise specified, primary mediastinal large B-cell lymphoma, high grade B-cell lymphoma, and DLBCL arising from follicular lymphoma. • Adult patients with relapsed or refractory follicular lymphoma (FL) after two or more lines of systemic therapy.*

Summary	
Effective Date of Policy:	2/23/2026
Applicable Agents	Abecma® (idecabtagene vicleucel), Aucatzyl® (obecabtagene autoleucel), Breyanzi® (lisocabtagene maraleucel), Carvykti® (ciltacabtagene autoleucel), Kymriah® (tisagenlecleucel), Tecartus® (brexucabtagene autoleucel), Yescarta® (axicabtagene ciloleucel)
Approval Timeframe	6 months

This policy applies to all CAR-T therapies for oncologic indications, including new to market agents not listed above.

Required Criteria for Initial Approval

All of the following conditions for the requested indication must be met in order to approve therapy:

Indication	Inclusion Criteria	Recommended Dosing Regimen
Refer to specific product for indication	1. Documented FDA approved indication per prescribing information or supported evidence per NCCN guidelines 2. Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1 3. Must be prescribed by a Hematologist or Oncologist 4. Must be ≥ 18 years of age	• Refer to FDA prescribing information

Exclusion Criteria

- Therapy will not be covered if any of the below criteria are met:
  - Use as first-line therapy
  - Indication not approved by the FDA and/or supported by NCCN guidelines
  - Any central nervous system (CNS) disease (for example, brain metastases, CNS lymphoma, and a history or presence of CNS disorders such as seizure disorder, cerebrovascular ischemia/hemorrhage, dementia, cerebellar disease, or autoimmune disease with CNS involvement)
  - History of allogeneic stem cell transplant, chimeric antigen receptor therapy, or other genetically modified T-cell therapy

Continuation Criteria

Enrollee will be eligible for one lifetime, single administration of CAR-T therapy. Additional treatment with CAR-T therapy will not be covered. Retreatment is considered Experimental/Investigational when any FDA approved CAR-T therapy, or any other CAR-T therapy still under investigation, has been previously administered.

Considerations

- Please refer to the package insert for detailed dosing information.
- Prior authorization is obtained through the CDPHP pharmacy department.
- Prescription drug benefit is not required for this therapy
- Must be administered at an FDA-certified center
- Some products require failure to systemic therapies. Some of the commonly used agents are listed below for reference in Table 1.

Table 1.

Proteasome inhibitors	Immunomodulatory agents	Anti-CD38 monoclonal antibodies
Kyprolis (carfilzomib)	Thalomide (thalidomide)	Darzalex (daratumumab)
Velcade (bortezomib)	Revlimid (lenalidomide)	Sarclisa (isatuximab)
Ninlaro (ixazomib)	Pomalyst (pomalidomide)	

Administration, Retreatment, and Treatment with Additional or Other Gene/Cellular Therapies

- One-Time Administration
  - Most gene and cellular therapies, whether autologous, allogeneic ("off-the-shelf"), or in vivo gene-transfer therapies, are designed and studied as one-time treatments.
  - Repeat dosing, reinfusion, or sequential therapy with other gene or cellular products has not been established as safe, effective, or clinically appropriate.
- Retreatment/Repeat Administration
  - Retreatment with the same gene or cellular therapy product is considered experimental and investigational because:
    - Clinical trials evaluated these therapies as single-administration interventions
    - Safety, efficacy, and durability of a second administration have not been established
    - Risks of immune activation, insertional mutagenesis, or vector immunity may be increased with repeat dosing
- Treatment with an Additional or Other Gene/Cellular Therapy
  - Treatment with an additional or different gene or cellular therapy after prior exposure to any gene or cellular therapy is also considered experimental and investigational, unless supported by evidence demonstrating:
    - Anticipated clinical benefit beyond available standard therapies
    - Safety of sequential administration
    - Justification for selecting a second gene/cellular intervention after a prior one
    - Meets the criteria established in the Off-Label Use of FDA Approved Drugs 1350/20.000048
  - This includes, but is not limited to:
    - Switching between CAR-T products (e.g., CD19 → CD19 or CD19 → BCMA)
    - Switching between autologous and allogeneic cellular therapies
    - Sequential use of CAR-T, TCR-T, NK-cell therapies, or other genetically engineered cell therapies
    - Receiving a gene therapy after previous gene or cellular therapy exposure
    - Receiving an in vivo gene therapy following any prior vector-based therapy
- Prior Gene/Cell Therapy Exposure
  - An individual is generally not eligible for additional gene or cellular therapy if they have previously received:
    - Any autologous cellular therapy (e.g., CAR-T, TCR-T, TIL),
    - Any allogeneic genetically modified cellular therapy,
    - Any in vivo gene therapy (e.g., AAV, lentiviral vector)
    - Any ex vivo gene-modified cell product
    - Are being considered for any other gene or cellular therapy without documented evidence supporting safety and anticipated benefit.
- Coverage Determination
  - Absent peer-reviewed evidence demonstrating safety and benefit, retreatment or sequential therapy is considered investigational and will not be covered.

GOVERNMENT PROGRAMS

CHILD HEALTH PLUS: Subject to all terms and conditions noted in above application.

MEDICARE ADVANTAGE: Please follow the national coverage determination guidelines included in the link below: https://www.cms.gov/medicare-coverage-database/details/ncddetails.aspx?ncdid=374&bc=CAAAAAAAAAAA

SELECT/HARP PLAN: Subject to all terms and conditions noted in above application.

CDPHP Pharmacy Services 2/23/2026

New: 2/2024

Revised	Reviewed
2/2025, 9/2025, 2/2026	

Revision Date	Changes Made
2/2025	Added Auctazyl (obecabtagene autoleucel) to policy and updated indications for Breyanzi and Yescarta following FDA accelerated pathway approval
9/2025	Requirement for treatment at a "Certified Treatment Center" has been removed from all drug-specific criteria Added J-codes for each agent Updated approval timeframe to 6 months Added provider and age requirement
2/2026	Added in considerations regarding Administration, Retreatment, and Treatment with Additional or Other Gene/Cellular Therapies Added new Breyanzi indication for marginal zone lymphoma
2/2026	Updated indication for Carvykti

MEDICAL POLICY

Medical Policy Title	**Chimeric Antigen Receptor T-Cell (CAR-T) Therapy for Candidate Selection**
Policy Number	**7.02.11**
Current Effective Date	**7/1/2026**
Next Review Date	**December 2027**

Our medical policies are based on the assessment of evidence based, peer-reviewed literature, and professional guidelines. Eligibility for reimbursement is based upon the benefits set forth in the member's subscriber contract. (Link to Product Disclaimer)

This policy only applies to an individual if the CAR-T therapy drug has first been approved by the Health Plan Pharmacy.

POLICY STATEMENT(S)

I. Chimeric antigen receptor T-cell (CAR-T) therapy is **medically appropriate** for carefully selected candidates after drug approval by the Health Plam pharmacy and **ALL** of the following criteria are met:

   A. Individual is using as a one-time treatment;

   B. Multidisciplinary team has evaluated the individual and recommends treatment (see policy guidelines for required documentation);

   C. Individual has adequate organ function with no significant deterioration in organ function expected within four (4) weeks after apheresis.

II. CAR-T therapy is **not medically necessary** for individuals that have had a recent allogeneic transplant unless specifically permitted by the product labeling.

RELATED POLICIES

POLICY GUIDELINE(S)

I. Required documentation from the multidisciplinary team that includes the individual's eligibility and risk for CAR-T therapy should include:

   (*Based on FDA approved indications, additional testing and documentation may be necessary to support the use of the medication.)

   A. Place of Service (POS)

      1. Outpatient admission;

      2. If inpatient admission is being requested, include documentation explaining why outpatient services are not appropriate or sufficient for the individual's care;

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

B. Clinical Evaluation
    1. Risk benefit analysis completed by treatment center;
    2. Confirmation of diagnosis;
    3. Identification of comorbidities;
    4. Management of co-morbidities;
    5. Current assessment of co-morbidities;
    6. Consult notes (if applicable);

C. Psycho-Social Evaluation
    1. Identification of stressors;

D. Performance Status
    1. Karnofsky performance score;
    2. Palliative Performance Scale (PPS) score); or
    3. Eastern Cooperative Oncology Group (ECOG) performance status;

E. Lab Tests
    1. CBC;
    2. Metabolic profile;
    3. Serologies: CMV, Hepatitis B and C;
    4. HIV testing;

F. Cardiac Assessment
    1. 12 Lead EKG;
    2. Echo or Muga Scan;

G. Pulmonary Assessment
    1. Chest X-ray;
    2. Pulmonary function tests (PFTs) for high-risk for respiratory failure (COPD, emphysema, a-1-antritrypsin deficiency, hepatopulmonary syndrome, or significant smoking history);

H. Age-Appropriate Screening Tests
    1. Please refer to the U.S Preventive Services Task Force (USPSTF) website for list of age-appropriate screening guidelines. https://uspreventiveservicestaskforce.org/uspstf/ [accessed 2025 Sep 17]

DESCRIPTION

CAR T-cell therapy is a form of cancer immunotherapy that involves genetically engineered T-cells. CAR-T therapy is used to treat some types of recurrent blood cancers such as B-cell acute lymphoblastic leukemia (ALL), diffuse large B-Cell lymphoma, follicular lymphoma, high-grade B-cell lymphoma, mantle cell lymphoma, multiple myeloma and primary mediastinal large B-Cell lymphoma.

The process typically begins with the collection of an individual's white blood cells through leukapheresis. These cells are then activated and genetically modified usually via retroviral or lentiviral transduction to express a chimeric antigen receptor that targets cancer cells. Once engineered, the CAR T-cells are expanded to clinically effective quantities, undergo rigorous quality control testing, and are cryopreserved.

Commercial CAR T-cell products are manufactured at centralized facilities, requiring the transport of the individual's apheresis material to the manufacturing site and the final CAR T-cell product back to the treatment center. Before infusion, individuals typically receive lymphodepleting chemotherapy to optimize the immune environment for CAR-T-cell function. The therapy is administered as a single intravenous infusion. Several CAR T-cell products have received FDA approval for the treatment of specific types of hematological malignancies.

SUPPORTIVE LITERATURE

Haslam et al (2023) sought to estimate how many individuals in the U.S. with advanced or metastatic cancer are eligible for and likely to respond to CAR T-cell therapy, based on FDA-approved indications and clinical trial data. In 2017, approximately 2.7% of patients were estimated to be eligible for CAR T-cell therapy, with 2.0% potentially able to respond. By 2023, eligibility increased to 3.9%, with the highest rates seen in large B-cell lymphoma (2.5%) and the lowest in mantle cell lymphoma (0.1%). The estimated response rate also rose to 3.4% in 2023, again with large B-cell lymphoma showing the highest potential response (2.1%). Across pivotal trials, the median response rate was 66.4%, ranging from 25.5% to 98%. However, most approvals were based on single-arm studies using surrogate endpoints, with only two randomized trials demonstrating survival benefits. While CAR T-cell therapies show promising response rates, the overall proportion of eligible and responsive patients among those with advanced cancers remains relatively low.

Pasqui et al (2022) conducted a systematic review to assess the efficacy and safety of CAR T-cell therapy in patients with hematological malignancies. The review included seven parallel randomized controlled trials (RCTs) comparing CAR-T therapy to standard treatments, encompassing a total of 2,464 patients. However, only three trials focused on B-cell lymphomas had available outcome data at the time of analysis. The study found adverse events were frequent but not significantly different from those observed with standard therapies. Survival and progression-related outcomes were supported by low to very low certainty of evidence. Quality of life outcomes were not reported in the available data. The authors concluded that current evidence is insufficient to support the routine use of CAR T-cell therapy outside of clinical trials or compassionate use settings.

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

CD19-directed CAR T-cell therapy has shown high initial response rates in children and young adults with relapsed or refractory B-cell acute lymphoblastic leukemia (B-ALL), although relapse remains common.

Shah et al (2021) conducted a phase I trial using autologous CD19.28z CAR T-cells in 50 patients, evaluating both treatment response and long-term outcomes. Overall, 62% achieved complete remission (CR), with 90.3% of those being minimal residual disease (MRD)-negative. Patients who received fludarabine/cyclophosphamide (Flu/Cy) lymphodepletion had significantly better outcomes (69% CR) compared to alternative regimens (25%). Cytokine release syndrome (CRS) occurred in 70% of patients, with 18% experiencing severe cases; neurotoxicity was seen in 20%, but all resolved. The therapy was also effective in patients with central nervous system (CNS) involvement. Median overall survival (OS) for the full cohort was 10.5 months, but among those who underwent allogeneic hematopoietic stem cell transplant (alloHSCT) after achieving MRD-negative CR, median OS extended to 70.2 months, with a 5-year event-free survival (EFS) of 61.9% and a relapse rate of only 9.5%. All MRD-negative CR patients who did not receive alloHSCT relapsed. These findings support the use of sequential CD19.28z CAR T-cell therapy followed by alloHSCT for durable disease control in high-risk pediatric and young adult B-ALL patients, with Flu/Cy lymphodepletion showing superior efficacy and CAR T-cell therapy proving feasible even in cases with active CNS disease.

PROFESSIONAL GUIDELINE(S)

The National Institute for Health and Care Excellence (NICE) provides evidence-based guidance on FDA approved CAR-T treatments for bone marrow and blood cancers, including diffuse large B-cell lymphoma and B-cell acute lymphoblastic leukemia (see reference section for drug specific recommendations from NICE).

National Comprehensive Cancer Network guidelines for B-Cell Lymphomas V3.2025 states that "if patients intend to receive CAR T-cell therapy or CD3 x CD20 bispecific antibody therapy, bendamustine should be used with caution. Delay bendamustine until after CAR-T leukapheresis."

Epperla et al (2023) reported the American Society for Transplantation and Cellular Therapy (ASTCT) Clinical Practice Guidelines for Transplantation and Cellular Therapies in Diffuse Large B Cell Lymphoma. The recommendations state:

- "CAR-T therapy (axi-cel or lisocel) as a standard of care option in DLBCL refractory to first-line chemoimmunotherapy or relapsed within 12 months of first-line chemoimmunotherapy (grade A recommendation)."
- "CAR-T therapy in patients with late relapse who have not achieved remission after second-line therapies (grade A recommendation)."
- "CAR-T therapy in those who are not eligible for autologous-HCT because of comorbidities or age regardless of the timing of relapse (grade B recommendation)."

- "Does not consider secondary CNS involvement a contraindication for administering CAR-T therapy (grade B recommendation)."

Dhakal et al (2022) reported the ASTCT Clinical Practice Recommendations for Transplantation and Cellular Therapies in Multiple Myeloma. The recommendations state:

- "The exact timing and sequencing of therapies like CAR-T in the context of stem cell transplantation and other therapies is not established yet."

Iqbal et al (2024) reported the Clinical Practice Recommendations for Hematopoietic Cell Transplantation and Cellular Therapies in Follicular Lymphoma (FL). This was a collaborative effort on behalf of the ASTCT and the European Society for Blood and Marrow Transplantation. The recommendations state:

- "The panel does not recommend consolidation with CAR T-cell therapy ineligible FL patients incomplete or partial remission after first line therapies, outside the setting of a clinical trial."
- "The panel does not recommend commercially available CAR T-cell therapy ineligible, relapsed (within less than 24 months from receiving chemotherapy and without evidence of histological transformation) FL patients who have achieved complete or partial remission after second line therapies."
- The panel recommends considering CAR T-cell therapy in eligible, relapsed FL patients who have relapsed after an autologous transplant and did not achieve complete or partial remission to most recent anti-lymphoma treatment.
- "The panel recommends CAR T-cell therapy as a treatment option for patients who did not achieve complete or partial remission after second or subsequent line therapies."
- "The panel recommends CAR T-cell therapy ineligible, relapsed FL patients who have relapsed after allogeneic transplant and are untreated or did not achieve complete or partial remission to most recent anti-lymphoma treatment."

Kharfan-Dabaja et al (2025) reported the ASTCT Clinical Practice Recommendations on the Role of Allogeneic Hematopoietic Cell Transplantation and CAR-T Therapy in Patients with Chronic Lymphocytic Leukemia. The recommendations state:

- "The panel recommends CAR T-cell therapy in CLL patients whose disease relapsed and/or was refractory to both a covalent BTK inhibitor and a BCL-2 inhibitor and either responded or did not respond to a noncovalent BTK inhibitor."
- "The panel recommends CAR T-cell therapy for CLL patients whose disease relapsed and/or was refractory to both a covalent BTK inhibitor and a BCL-2 inhibitor."
- "The panel recommends CAR T-cell therapy in CLL patients that relapse after an allo-HCT."

REGULATORY STATUS

For recommendations related to FDA-approved CAR-T therapies, refer to the National Institute for Health and Care Excellence (NICE), which provides evidence-based guidance on CAR-T treatments for bone marrow and blood cancers, including diffuse large B-cell lymphoma and B-cell acute lymphoblastic leukemia (see reference section for drug specific recommendations from NICE).

CAR T-cell therapies that have been approved by the FDA for the treatment of various hematologic malignancies can be found on Pharmacy Policy-103. Available from: https://provider.excellusbcbs.com/documents/d/global/chimeric-antigen-receptor-t-cell-car-t-therapy [accessed 2025 Nov 10]

Drugs

The United States Food and Drug Administration (FDA) is responsible for ensuring the safety, efficacy, and quality of drugs sold in the United States. This includes both prescription and over-the-counter medications. Refer to the FDA Drug website. Available from: https://www.fda.gov/drugs [accessed 2025 Nov 10]

The FDA maintains information for consumers and health professionals on new drug warnings and other safety information, drug label changes, and shortages of medically necessary drug products. Available from: Drug Safety and Availability | FDA [accessed 2025 Nov 10]

Vaccines, Blood, and Biologics

The United States Food and Drug Administration (FDA) regulates vaccines, blood and blood products, and biologics via the Center for Biologics Evaluation and Research (CBER) which ensures the safety, efficacy, and quality of these products. Refer to the FDA vaccines/blood/biologics website. Available from: https://www.fda.gov/vaccines-blood-biologics [accessed 2025 Nov 10]

The FDA maintains information for consumers and health professionals on vaccine, blood and biologics warnings and other safety information. Available from: Recalls (Biologics) | FDA [accessed 2025 Nov 10]

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).

MEDICAL POLICY

Medical Policy Title	**Chiropractic Care**
Policy Number	**10.01.02**
Current Effective Date	**January 1, 2026**
Next Review Date	**July 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Chiropractic care is considered **medically appropriate** for diagnosis and management of neuromusculoskeletal conditions, within the boundaries set by state licensure, by a licensed Doctor of Chiropractic (DC).

II. Chiropractic care is considered **medically appropriate** when **ALL** of the following criteria are met:

   A. There is documented history, examination, and diagnosis of a neuromusculoskeletal condition;

   B. There is a reasonable expectation of recovery or improvement in function;

   C. Treatment is provided in accordance with standards of generally accepted chiropractic practice;

   D. The diagnostic procedures and therapeutic interventions are clearly related to the patient's symptoms/condition being treated;

   E. Individualized treatment plans incorporate objective measures of patient-based outcomes.

III. Maintenance care begins when the therapeutic goals of a treatment plan have been achieved or when no additional functional progress is apparent or expected to occur. Maintenance care is considered **not medically necessary**.

IV. Chiropractic care is considered **not medically necessary** as a treatment intervention to restore spinal curves or in treatment of idiopathic scoliosis in an asymptomatic patient.

V. Routine or repeat X-ray use to assess the function or structure of the spine is considered **not medically necessary** in the absence of red flags or clinical reasons to suspect serious underlying pathology.

VI. Chiropractic care is considered **investigational** when it is rendered for non-neuromusculoskeletal conditions (e.g., infantile colic, childhood asthma, hypertension, primary dysmenorrhea).

11.01.03 Experimental or Investigational Services

POLICY GUIDELINE(S)

I. Coverage of chiropractic care is limited to medically necessary services provided by a licensed DC, within the scope of their license, in connection with the detection or correction of spinal misalignment or mechanical/myofascial extremity pain.

II. Contraindications include, but are not limited to, recent compression fracture, severe osteoporosis, inflammatory arthropathy in the active systemic stage, or locally if acute inflammation is present, infections, cauda equina syndrome, progressive or sudden neurological deficit and visceral disease.

III. All chiropractic care is subject to retrospective utilization review for determining medical necessity. Coverage for services determined to be not medically necessary will be denied.

IV. Examples of red flags, which may indicate the possibility of a more serious underlying condition, include back pain and/or back pain with radiculopathy in one or more of the following settings:

   A. History of cancer,
   B. Unexplained weight loss,
   C. Immunosuppression,
   D. Urinary infection,
   E. Intravenous drug use,
   F. Prolonged use of corticosteroids,
   G. Back pain not improved with conservative management,
   H. History of significant trauma,
   I. Minor fall or heavy lift in a potentially osteoporotic or elderly individual,
   J. Prolonged use of steroids,
   K. Acute onset of urinary retention or overflow incontinence,
   L. Loss of anal sphincter tone or fecal incontinence,
   M. Saddle anesthesia, or
   N. Global or progressive motor weakness in the lower limbs.

DESCRIPTION

Chiropractic is a health care profession that focuses on disorders of the musculoskeletal system (primarily the spine) and the nervous system, and their effects on general health. Chiropractic

services are used to treat neuromusculoskeletal complaints, including, but not limited to, back pain, neck pain, pain in the joints of the arms or legs, and headaches. DCs, often referred to as chiropractors, practice a hands-on, drug-free approach to health care that includes patient examination, diagnosis, and treatment. Chiropractors have broad diagnostic skills and are trained to recommend therapeutic and rehabilitative exercises, as well as to provide nutritional, dietary, and lifestyle counseling.

One of the most common and well-known therapeutic procedures performed by DCs is spinal manipulation (sometimes referred to as a "chiropractic adjustment"). The purpose of spinal manipulation is to restore joint mobility by manually applying a controlled force into joints that have become hypomobile – or restricted in their movement – as a result of a tissue injury or restriction. Manipulation, or adjustment, of the affected joint and tissues, restores mobility, potentially alleviating pain, and muscle tightness, and restoring function.

SUPPORTIVE LITERATURE

Chiropractic care has been utilized for the treatment of idiopathic scoliosis' however, scientific evidence is limited, and the efficacy of manual therapy for correcting the scoliotic curve or progression of the curve has not been established in the peer-reviewed published scientific literature. Chiropractic manipulation may be used to improve joint mobility and relieve pain associated with scoliosis.

Plain film radiographs should not be used as a screening procedure without clinical indications. The decision for radiographic re-examination should be based on patient symptoms, physical findings, and the potential impact of the results of the examination on the treatment plan and on the net health outcome for the patient. A literature review performed by Corso et al (2020) did not identify any relevant studies that investigated the diagnostic or therapeutic utility of cervical, thoracic, or lumbar radiographs (in the absence of red flags) for the functional or structural evaluation of the spine. Similarly, Jenkins et al (2018) found limited evidence to support routine spinal X-rays and strong evidence to support potential harms associated with routine spinal X-rays. Without indicators of serious pathology, the increase in information available from X-ray adds little additional benefit to patient health, and may unnecessarily increase patient concern, increase the risk of developing chronic pain, contribute to fear-avoidance behaviors, and contribute to low-value care.

The long-term safety and effectiveness of the use of chiropractic management and manual therapies in the treatment of non-neuromusculoskeletal conditions, including but not limited to hypertension, asthma, colic, and otitis media have not been proven in the medical literature through quality research, such as long-term, randomized, controlled clinical trials. A systematic review was conducted during a Global Summit in September 2019 to evaluate the medical literature on the use of spinal manipulative therapy (SMT) to manage non-musculoskeletal disorders (Cote 2021). Based on six randomized controlled trials, SMT was found to not be superior to sham interventions for the treatment of non-musculoskeletal disorders. The researchers concluded there is no evidence of an effect of SMT for the management of non-musculoskeletal disorders including infantile colic, childhood asthma, hypertension, and primary dysmenorrhea.

Cabanillas-Barea et al (2023) conducted a systematic review and meta-analysis that evaluated the effectiveness of osteopathy and chiropractic techniques in reducing crying time and increasing sleep time in babies with infantile colic. The outcome measures were hours spent crying and/or sleeping. Five studies with 422 babies total were evaluated. Complementary treatments failed to decrease the crying time (mean difference -1.08, 95% CI: -2.17 to 0.01) and to increase sleeping time (mean difference 1.11, 95% CI: -0.20 to 2.41) compared with no intervention. Authors concluded that osteopathy and chiropractic treatment failed to reduce the crying time and increase sleeping time in babies with infantile colic, compared to no additional intervention.

Trager et al (2026) conducted an evidence-based clinical practice guideline development study for the chiropractic management of adults with cervicogenic headache (CGH) and tension-type headache (TTH). The authors performed an umbrella review of systematic reviews and clinical practice guidelines on nonpharmacological interventions for adults with CGH or TTH published from 2017 to August 2023. Thirty-two relevant articles (31 systematic reviews and 1 clinical practice guideline) were identified and considered "high" or "acceptable" quality. Strong recommendations for CGH chiropractic management include offering spinal manipulation and offering multimodal therapy that includes spinal manipulation and any combination of joint mobilization, soft tissue, and/or modalities. Strong recommendations for TTH management include providing spinal manipulation combined with joint mobilization, soft tissue techniques, and/or modalities, and offering joint mobilization and/or soft tissue techniques. The authors concluded that Chiropractors may appropriately care for individuals with CGH and TTH using a variety of nonpharmacological interventions, including the use of spinal manipulative therapy for patients with CGH, whereas patients with TTH should receive spinal manipulative therapy as a component of multimodal care.

REGULATORY STATUS

New York State law requires that contracts providing physician services, medical, major medical, or similar comprehensive-type coverage, shall include coverage for chiropractic care. Chiropractic care in New York State is defined as detecting and correcting structural imbalance, distortion, or subluxations in the human body through manual or mechanic means, for the purpose of removing nerve interference effects related to distortion, misalignment, or subluxation of or in the vertebral column.

The United States Food and Drug Administration (FDA) regulates medical devices. All devices including related components require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2026 Jun 11]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most serious type of recalls on our website by the date that the FDA posts the information on our website.

Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: CLINICAL PEER REVIEWERS

POLICY EFFECTIVE DATE:	12/1/2023
Policy Control #:	1370/20.000270
Next Annual Review:	November, 2026

DISCLAIMER

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgement when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice,

DESCRIPTIONS

Process used to identify the eligibility and use of licensed physicians to serve as clinical peer reviewers for utilization review decisions, and other health care professionals as clinical peer reviewers. For the purposes of this policy, unless otherwise specified, the term "clinical peer reviewer" will apply to a physician.

RELATED POLICIES/DOCUMENTS

Resource Coordination Policies:

- Review Process for Resource Coordination, 1370/20.000213.

POSITION STATEMENT

CDPHP utilizes clinical peer reviewers when a CDPHP medical director has reviewed a request for service and feels they do not have the clinical expertise to render the determination.

A clinical peer reviewer is:

- A physician who possesses a current and valid non-restricted license to practice medicine **OR**
- A health care professional other than a licensed physician who:
    - Where applicable, possesses a current and valid non-restricted license, certificate, or registration or where no provision for a license, certificate or

registration exists, is credentialed by the national accrediting body appropriate to the profession; **AND**

- Is in the same profession and same or similar specialty as the health care provider who typically manages the medical condition or disease or provides the health care service or treatment under review.

A clinical peer reviewer making a determination on mental health or substance use disorder (SUD) treatment is either:

- A physician who possesses a current and valid non-restricted license to practice medicine and who specializes in behavioral health and has experience in the delivery of mental health or SUD treatment; or

- A health care professional other than a physician who specializes in behavioral health and has experience in the delivery of mental health or SUD treatment and, where applicable, possesses a current and valid non-restricted license, certificate, or registration, or if none exists, is credentialed by the national accrediting body appropriate to the profession.

A clinical peer reviewer making a determination involving treatment of a medically fragile child is:

- A physician who possesses a current and valid non-restricted license to practice medicine and who is board certified or board eligible in pediatric rehabilitation, pediatric critical care, or neonatology
- A physician who possesses a current and valid non-restricted license to practice medicine and is board certified in a pediatric subspecialty directly relevant to the patients medical condition

Only a clinical peer reviewer may determine that the request will be denied.

The clinical peer reviewer must consider all clinical information available to him/her, including the specific needs of the member, available practice guidelines, applicable contract benefits and supporting resource coordination policies and procedures, and assessment of the network delivery system.

POLICY CONSIDERATIONS

If the internal clinical peer reviewer does not feel qualified to review a particular case, an external clinical peer reviewer will be identified from the list of qualified board-certified practitioners.

A health care professional providing health care services to an enrollee will be prohibited from

serving as the clinical peer reviewer for such enrollee in connection with the health care services being requested.

The chosen external clinical peer reviewer will receive a letter outlining the responsibilities of a clinical peer reviewer, an appropriate case summary, and all relevant materials blinded as to the identity of the involved enrollee if no business associate agreement has been signed.

The decision of the clinical peer reviewer will be documented in writing and timely, in accordance with the appropriate applicable regulatory guidelines.

CDPHP renders the final determination based on all information presented including but not limited to the opinion of the clinical peer reviewer.

CDPHP PRODUCT VARIATIONS

CHILD HEALTH PLUS	Subject to all terms and conditions noted above in the policy.
MEDICARE ADVANTAGE	Subject to all terms and conditions noted above in the policy.
SELECT PLAN/HARP	Subject to all terms and conditions noted above in the policy.

October 1, 2026

CLINICAL REVIEW PREAUTHORIZATION LIST

The following services may require preauthorization regardless of place of service for the following lines of business:
Commercial products, Essential Plan, Medicare, and Managed Safety Net Products.
Please review the column that applies to the member's specific line of business.

Code Changes Are Highlighted In Grey

IMPORTANT
This list represents those services that require preauthorization with a clinical medical necessity review. Certain services require preauthorization or notification without requiring clinical review.
It is NOT inclusive of all insurance products and procedures requiring preauthorization.
If you have a strategic account, call Customer Care for PA requirements at:
(518) 641-3100 or toll free 1-877-724-2579
Mon. - Fri. 8 a.m. to 5 p.m.

Please verify specific coverage requirements before rendering service.

Please Note: There are some codes that require PA by diagnosis. These additional diagnosis details are included in the last column of this document.

If a code on this list is part of one of the below listed Resource Coordination policies, check the policy for more codes or special prior authorization rules:
• Dental Services Covered Under the Medical Benefit, 1370/20.000417
• Dental Services: Criteria for Use of Hospital Inpatient or Outpatient Ambulatory Facility Services, 1370/20.000181
• Durable Medical Equipment, Prosthetics/Orthotics & Medical Supplies, 1370/20.000509
• Inpatient Rehabilitation: Acute, Subacute, and Skilled: 1370/20.000204
• Second Opinions, 1370/20.000159
• Transitional Care – New Enrollee, 1370/20.000194
• Transitional Care – Provider Leaves the Network, 1370/20.000195

The Category column identifies the medical category associated with a specific procedure code. By using either, the category listed on the PDF or the procedure code itself, users can navigate to the Corporate Medical Policy page: https://provider.cdphp.com/resources/medical-policies **to view all applicable medical policies within that category or related to the selected code.**
Please note that the medical necessity criteria applied during the review process are dependent on the member's plan and may not be outlined in a Corporate Medical Policy.
In some cases, criteria may instead be derived from InterQual®, eMedNY, or CMS guidelines.

To initiate preauthorization requests please follow the below service contact information:

Behavioral Health, Medical & Durable Medical Equipment:

UTILIZATION MANAGEMENT STANDARD
CLINICAL REVIEW PREAUTHORIZATION LIST

The following services may require preauthorization regardless of place of service for the following lines of business:
Commercial products, Essential Plan, Medicare, and Managed Safety Net Products.
Please review the column that applies to the member's specific line of business.

Code Changes Are Highlighted In Grey

IMPORTANT

This list represents those services that require preauthorization with a clinical medical necessity review. Certain services require preauthorization or notification without requiring clinical review.
It is NOT inclusive of all insurance products and procedures requiring preauthorization.
If you have a strategic account, call Customer Care for PA requirements at:
(518) 641-3100 or toll free 1-877-724-2579
Mon. - Fri. 8 a.m. to 5 p.m.

Please verify specific coverage requirements before rendering service.

Please Note: There are some codes that require PA by diagnosis. These additional diagnosis details are included in the last column of this document.

The Category column identifies the medical category associated with a specific procedure code. By using either, the category listed on the PDF or the procedure code itself, users can navigate to the Corporate Medical Policy page: https://provider.cdphp.com/resources/medical-policies **to view all applicable medical policies within that category or related to the selected code.**
Please note that the medical necessity criteria applied during the review process are dependent on the member's plan and may not be outlined in a Corporate Medical Policy.
In some cases, criteria may instead be derived from InterQual®, eMedNY, or CMS guidelines.

To initiate preauthorization requests please follow the below service contact information:

Behavioral Health, Medical & Durable Medical Equipment:
Please go to the Provider Portal by going to this URL,
https://provider.cdphp.com

Health Help:
Phone Requests: Phone: 1-888-673-7038, Monday through Friday from 8:00 a.m. – 6:00 p.m.
Internet Request: https://www.healthhelp.com/guidelines/
Fax Requests:
STAT Case Request: PROD -866-872-1616
Standard Case Request: PROD -866-872-1611
Clinicals: PROD -866-872-1571
