Treatment for CALD is extremely limited. For individuals with adrenal insufficiency, corticosteroid replacement therapy is essential. Management of spinal cord disease, urinary complications, polyneuropathy tend to follow standard accepted guidance. Allogeneic hematopoietic stem cell transplantation (HSCT) for the treatment of certain individuals, particularly young boys, or adolescents with evidence of central nervous system involvement who are early in the course of the disease and have no neurological symptoms is currently standard of care and only existing effective therapy to stop progression of neurological symptoms in childhood. While studies have shown that a HSCT stops the progression of neurological disease in ALD, although it does not improve adrenal insufficiency. HSCT is a major medical procedure that carries significant risk. Since Allogeneic HSCT is only effective in early stages of the disease, it is pertinent that newborn screening is expanded to all states and that all boys diagnosed with ALD undergo repeated brain MRI studies and follow up routinely with a neurologist.

Elivaldogene autotemcel (Eli-Cel) uses ex vivo transduction with the Lenti-D lentiviral vector (LVV) to add functional copies of the ABCD1 gene into a patient's own hematopoietic stem cells (HSCs). The addition of the functional ABCD1 gene allows patients to produce the ALD protein (ALDP), which is thought to facilitate the breakdown of very long-chain fatty acids (VLCFAs). This expression of the ALDP and the effect to is stop progression of CALD and preserve as much neurologic function as possible, for as long as possible (expected to be life-long). Eli-Cel is specifically being proposed for treatment of early active cerebral adrenoleukodystrophy (CALD) in patients less than 18 years of age who do not have an available and willing human leukocyte antigen (HLA)-matched sibling hematopoietic stem cell (HSC) donor.

Clinical Trial experience for Eli-Cel includes Phase 2/3 Starbeam study (ALD-102) and the Phase 3 ALD-104 study (ongoing, no results posted). Additionally, bluebird bio is conducting a long-term safety and efficacy follow-up study (LTF-304) for patients who have received Eli-Cel for CALD and completed two years of follow-up in ALD-102 or ALD-104. In ALD-102, 90.6% (29/32) of patients met the primary endpoint of Major Functional Disabilities (MFD)-free survival at 24 months. As previously reported, two patients withdrew from study ALD-102 at investigator discretion, and one additional subject experienced rapid disease progression early after treatment, resulting in MFDs and subsequent death. All patients who completed ALD-102 enrolled in a long-term follow-up study (LTF-304). The median duration of follow-up is approximately four years (49 months; 13.4, 88.1).

Adverse reactions attributed to Eli-Cel observed in clinical trials include myelodysplastic syndrome, viral cystitis, pancytopenia, and nausea and vomiting. There have been no reports of graft-versus-host-disease, graft failure or rejection, transplant-related mortality, or replication competent lentivirus in the 67 patients who received Eli-Cel in clinical studies (ALD-102, ALD-104, LTF-304).

In June 2022, the Food and Drug Administration's (FDA) Cellular, Tissue, and Gene Therapies Advisory Committee (CTGTAC) discussed the use of Eli-Cel for early active CALD and determined the answer to the question, "Do the benefits of Eli-Cel outweigh the risks, for the treatment of any sub-population of children with early active cerebral adrenoleukodystrophy (CALD)?" with a vote of, CTGTAC voted 15 (yes) to 0 (no). Importantly, the FDA highlighted the safety issues that have been reported with Eli-Cel, including myelodysplastic syndrome (MDS), which emerged in 3 of 67 patients (4%) in clinical trials. The committee cautioned that this incidence is likely to increase due to the short duration of follow-up in the trials, however this did not dissuade their unanimous decision in support of therapy, weighing the risks and benefits.

The FDA granted approval under the accelerated approval pathway to Skysona on September 16, 2022, to slow the progression of neurologic dysfunction in boys 4–17 years of age with early, active cerebral adrenoleukodystrophy (CALD). This indication is approved under accelerated approval based on 24-month Major Functional Disability (MFD)-free survival. Continued approval for this indication may be contingent upon verification and description of clinical benefit in a confirmatory trial(s). The FDA prescribing information provided some additional information from the clinical trials, on limitations of use for Skysona. In patients who have a full deletion of ABCD1, an immune response may lead to a rapid loss of efficacy of Skysona, Skysona was not studied in patients with CALD secondary to head trauma, and patients with isolated pyramidal tract disease do not typically have clinical manifestations of disease until adulthood.

Summary	
Effective Date of Policy:	5/14/26
Indications	Treatment to slow the progression of neurologic dysfunction in boys 4-17 years of age with early, active cerebral adrenoleukodystrophy (CALD)
ICD10 Diagnosis Codes	E71. 520
HCPCS Code	J3387
Availability	*See FDA Prescribing Information*
Duration	Authorization will be for 6 months to allow sufficient time for administration

Required Criteria for Initial Approval

All of the following conditions for the requested indication must be met in order to approve therapy:

Specific Indication	Inclusion Criteria	Recommended Dosing

Indication
Slow the progression of neurologic dysfunction in boys 4-17 years of age with early, active cerebral adrenoleukodystrophy (CALD)
 	
ICD10: E71.520
	• Must be prescribed by an endocrinologist, neurologist, hematologist/oncologist, or prescriber who specializes in the management of cerebral adrenoleukodystrophy (CALD)
	• Must be 4-17 years of age
	• Must be designated male at birth
	• Must have a diagnosis of early, active cerebral adrenoleukodystrophy (CALD) defined as:
	  o Neurologic function score, NFS ≤ 1 AND
	  o Have gadolinium enhancement on brain magnetic resonance imaging (MRI) AND
	  o Loes scores of 0.5-9
	• Confirmed adenosine triphosphate binding cassette, sub family D, member 1 (ABCD1) gene mutation
	• Enrollee must NOT have a full ABCD1-gene deletion
		• One lifetime single-dose intravenous administration of Skysona (elivaldogene autotemcel)
		• The minimum recommended dose of Skysona is 5.0×10^6 CD34+ cells/kg
		• See FDA Prescribing Information for Dosing

	• Must have elevated very-long-chain fatty acid (VLCFA) values for all the following (see Appendix for VLCFA reference values in CALD):
	  o Concentration of C26:0
	  o Ratio of C24:0/C22:0
	  o Ratio of C26:0/C22:0
	• Enrollee must have negative serologic test for HIV infection (as per US FDA prescribing label, apheresis material from individuals with a positive test for HIV will not be accepted for Skysona manufacturing)
	• Enrollee has been screened for hepatitis B (HBV), hepatitis C (HCV), human immunodeficiency virus 1 & 2 (HIV-1/HIV-2) and human T-lymphotropic virus 1 & 2 (HTLV-1/HTLV-2) in accordance with clinical guidelines before collection of cells for manufacturing
	• Prescriber must attest ALL the following:
	  o Enrollee does NOT have a contraindication to the use of granulocyte colony stimulating factor (GCSF), plerixafor, busulfan, cyclophosphamide, fludarabine, or any other medicinal products required during myeloablative and lymphodepleting conditioning including hypersensitivity to the active substances or to any of the excipients AND
	  o Enrollee will avoid concomitant therapy with antiretroviral medications for at least one month prior to initiating medications for stem cell mobilization and for the expected duration for elimination of the medications, and until all cycles of apheresis are completed (Note: if a patient requires antiretroviral for HIV prophylaxis, confirm a negative test for HIV before beginning mobilization) AND
	  o Enrollee will receive periodic lifelong monitoring for hematological malignancies (including myelodysplastic syndrome (MDS)) AND
	  o Enrollee will NOT be administered vaccinations within the 6-weeks prior to the start of therapy and will NOT be administered concurrently while on therapy AND
	  o Enrollee is up to date with all age-appropriate vaccinations, in accordance with current vaccination guidelines, prior to initiating therapy AND
	  o Enrollee does not have a known and available human leukocyte antigen (HLA)-matched family donor AND
	  o Enrollee is clinically stable and eligible for hematopoietic stem cell transplantation
	  o Enrollee does NOT have isolated pyramidal tract disease
	  ▪ 1) NOTE: Patients with isolated pyramidal tract disease will be reviewed on a case-by-case basis
	  o Enrollee does NOT have an active infection, including clinically important localized infections AND
	  o Enrollee does NOT have an immediate family member with a known or suspected Familial Cancer Syndrome (including but not limited to hereditary breast and ovarian cancer syndrome, hereditary non-polyposis colorectal cancer syndrome, and familial adenomatous polyposis).	

Exclusion Criteria

Therapy will not be approved if any of the above Inclusion Criteria are not met OR any of the below noted Exclusion Criteria are met:

- Enrollee has previously received gene therapy
- Enrollee has had prior HSCT
- Enrollee has CALD secondary to head trauma
- Enrollee has available and willing 10/10 HLA-matched sibling donor (excluding female heterozygotes)
- Enrollee has active, uncontrolled HBV or HCV infection
- Enrollee has hematologic compromise including any of the following:
  - Peripheral blood absolute neutrophil count (ANC) < 1500 cells/mm^3, Platelets count < 100,000 cells/mm^3, Hemoglobin < 10 g/dL, an uncorrected bleeding disorder
- Enrollee has hepatic compromise including any of the following:
  - AST > 2.5x ULN, ALT > 2.5x ULN, Total bilirubin > 3 mg/dL (except if diagnosed with Gilbert's syndrome and otherwise stable)
- Enrollee has renal compromise as evidenced by a creatinine clearance (CrCl) < 50 mL/min OR estimated glomerular filtration rate (eGFR) < 70 mL/min/1.73 m2
- Therapy is being requested for treatment of adrenal insufficiency due to adrenoleukodystrophy

Continuation Criteria

- Not applicable, therapy is authorized only for one lifetime administration of Skysona (elivaldogene autotemcel). Authorization will be for 6 months to allow sufficient time for administration.
- Retreatment will be considered not medically necessary when any FDA approved gene therapy, or any other gene therapy under investigation, has been previously administered.

Considerations

- Prior authorization is obtained through the CDPHP pharmacy department.
- This indication is approved under accelerated approval based on 24-month Major Functional Disability (MFD)-free survival. Continued approval for this indication may be contingent upon verification and description of clinical benefit in a confirmatory trial(s).
- **Physician acknowledges that CDPHP will request documentation, not more frequently than biannually, of follow-up patient assessments including neuroimaging (i.e., MRI) and disability scale assessments (examples may include Major Functional Disability assessment, Neurologic Function Score) and others as required for monitoring of outcomes of therapy.**

VLCFA concentrations[3]

	Normal	Males with ALD	Women with ALD
C26:0 µmol/L	0.67 +/- 0.13	2.94 +/- 0.87	1.54 +/- 0.72
C24:0/C22:0 ratio	0.86 +/- 0.13	1.52 +/- 0.21	1.18 +/- 0.15
C26:0/C22:0 ratio	0.01 +/- 0.003	0.05 +/- 0.02	0.02 +/- 0.01

CDPHP Pharmacy Services 5/14/2026

New: 9/2022

Revised	Reviewed
9/2023, 9/2025, 12/2025, 5/2026	9/2024

Revision Date	Changes Made
9/2023	Updated to reflect FDA indication from prescribing information (PI), updated age and gender in inclusion criteria per FDA label, added exclusions from the limitations section of the PI, added normal levels for VLCFA table to considerations section.
9/2025	Added Loes score and provider attestations to inclusion criteria Added exclusion criteria enrollee has contraindication to conditioning regimen Removed exclusion of ejection fraction Removed inclusion ruling out additional possible causes
12/2025	Updated duration language - Authorization will be for 6 months to allow sufficient time for administration
5/2026	Re-worded and re-formatted policy criteria

MEDICAL POLICY

Medical Policy Title	**Sleep Studies**
Policy Number	**2.01.28**
Current Effective Date	**January 1, 2027**
Next Review Date	**January 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. A facility-based polysomnography (PSG) is considered **medically appropriate** for the evaluation of sleep disorders when **ANY** of the following are met:

- A. To diagnose sleep-related breathing disorders when home sleep testing is negative, inconclusive, or technologically inadequate;
- B. To assess the quality and quantity of night-time sleep in an individual with suspected narcolepsy or hypersomnia (PSG is performed the night prior to the Multiple Sleep Latency Test (MSLT);
- C. As a pre and post evaluation test for the U.S. Food & Drug Administration (FDA) approved hypoglossal nerve stimulation (e.g., Inspire) device;
- D. To diagnose sleep-related disorders in infants and children under 18 years of age whose medical records document **ONE or more** of the following:
  1. Observations of gross or subtle snoring (snoring may be of a continuous nature, rather than periodic as in adults);
  2. Cessation in breathing, difficulty breathing, and sleep disturbances;
  3. Symptoms associated with cardio-pulmonary;
  4. Growth delays;
  5. Behavior and/or developmental problems that are suspected to be caused by upper airway obstruction;
- E. When performed for individuals after standard evaluation is inconclusive and treatment decisions will be made based on the results of the study;
- F. When symptoms are of a severity which place the individual at risk for serious complications or injuries for **ANY** of the following indications:
  1. Neuromuscular disorders and sleep-related symptoms;
  2. Paroxysmal arousals or other sleep disturbances thought to be seizure-related;
  3. Sleep-related epilepsy that does not respond to conventional therapy;

4. Unexplained hypersomnolence;
5. Complicated/injurious parasomnias;
6. Periodic limb movement disorder;
7. Central nervous system (CNS) hypoventilation;
8. Chronic opioid medication misuse or abuse, including for individuals on a methadone maintenance program or a chronic pain treatment program;
9. Recent stroke or myocardial infarction (MI) within the last six (6) months;
10. Moderate or severe congestive heart failure (CHF) (NYHA Class III or IV);
11. Moderate (FEV1 between 50% and 80% of normal) or severe (FEV1 between 30% and 50% of normal) chronic obstructive pulmonary disease (COPD) with hypercapnia or hypoxemia;
12. Congenital syndromes (e.g., spina bifida) in an adult;
13. Cognitive deficits making understanding of instructions difficult;
14. Limb extremity impediments (missing or non-functioning);
15. BMI greater than or equal to 45 kg/m^2;
16. Drainage tubes in abdomen (e.g., post operative colostomy/urostomy);
17. Significant arrhythmias (not including atrial fibrillation);
18. Burns or wounds affecting significant portion of the abdomen;
19. Language barrier, where attempts to give instructions are unavailable or have failed;
20. Group home resident; elderly or disabled person;
21. Infant or child being considered for removal of a tracheostomy;
22. Infant or child with suspected congenital central alveolar hypoventilation syndrome or sleep-related hypoventilation due to neuromuscular disorders or chest wall deformities;
23. Child being considered for adenotonsillectomy to treat obstructive sleep apnea (OSA) syndrome; **or**
24. Male impotency for **EITHER** of the following indications:
    a. nocturnal penile tumescence test is positive; **or**
    b. brachiopenile impotence is suspected.

II. Follow-up or repeat facility-based PSG is considered **medically appropriate** in the following circumstances:

A. When a prior, medically necessary PSG that was appropriately prepared and performed was inadequate/not diagnostic due to limited sleep time or other variable (not an inconclusive or negative exam);

B. For the re-evaluation of an individual diagnosed with OSA with adequate treatment and persistent symptoms;

C. For individual with a current OSA diagnosis who is seeking to discontinue positive airway pressure, continuous positive airway pressure, automatic positive airway pressure (PAP/CPAP/APAP) therapy (e.g., as a result of expected symptom improvement after treatment);

D. To assess treatment response after surgical intervention for OSA or after initiation of an oral appliance to ensure therapeutic benefit;

E. After a substantial weight loss (10% of body weight) to determine whether CPAP is still needed at the previously titrated pressures;

F. After a substantial weight gain (10% of body weight) in an individual who has been treated successfully with CPAP/APAP and whose symptoms have returned, to assess whether pressure adjustments are needed;

G. To re-evaluate a pediatric individual diagnosed with OSA who:

1. After adequate treatment with tonsillectomy and/or adenoidectomy;
2. Compliance with PAP therapy and has continued signs and symptoms of OSA (including disturbed or restless sleep);
3. Has a high risk of having persistent OSA after tonsillectomy or adenoidectomy.

III. Split-night study is considered **medically appropriate** when criteria for PSG are met (refer to Policy Statement I or IV).

IV. A facility-based CPAP titration study is considered **medically appropriate** when criteria for PSG are met (refer to Policy Statement I) **AND** the individual has been diagnosed with **ANY** of the following indications:

A. Co-morbid conditions (e.g., COPD, asthma, documented neuromuscular disease, CHF with left ventricular ejection fraction (LVEF) less than 45%, cognitive impairment) and positive diagnosis of OSA;

B. Central sleep apnea; (e.g., central hypopnea/apnea greater than 50% of the total apnea hypopnea rate, or central hypopnea/apnea rate/index greater than five events per hour);

C. Mixed sleep apnea;

D. Significant hypoxemia defined as oxygen saturation less than or equal to 88% for a minimum of five continuous minutes during a two-hour diagnostic time period; **or**

E. Oxygen deficiency requiring supplemental oxygen.

V. An initial Multiple Sleep Latency Test (MSLT) is considered **medically appropriate** as a diagnostic tool when **ALL** of the following are met:

A. The individual is suspected of having narcolepsy or idiopathic hypersomnia, as evidenced by **ONE** of the following indications:

1. Excessive sleepiness;
2. Recurrent daytime naps or lapses into sleep daily for at least three months;
3. Cataplexy – the sudden loss of muscle tone occurring in association with intense emotion (e.g., laughing or crying);
4. Sleep paralysis, hypnagogic hallucinations, hypnopompic hallucinations, automatic behaviors, or disrupted major sleep episodes; **or**
5. Idiopathic hypersomnia;

B. The MSLT immediately follows a PSG that was negative for OSA, where total sleep time is greater than six (6) hours (however, it should not follow a split-night study);

C. The individual has not used stimulants, stimulant-like medications, sedatives, or REM-suppressing medications for two (2) weeks prior to the test or negative results on urine drug testing immediately preceding within a day of the study;

D. A comprehensive sleep evaluation, including established sleep disorder tools or questionnaires, has been performed;

AND EITHER of the following:

1. If OSA is suspected, a diagnostic study has been performed;

OR

2. OSA is present, therapy has been initiated and has resolved the individual's symptoms.

VI. Repeat MSLT testing is considered **medically appropriate** when **BOTH** of the following criteria are met:

A. The initial MSLT results are negative, ambiguous, or did not provide polygraphic confirmation after a properly performed test; **and**

B. The clinical history strongly indicates a diagnosis of narcolepsy or idiopathic hypersomnia's or when the response to treatment must be ascertained.

VII. Nocturnal pulse oximetry is considered **medically appropriate** when **ONE** of the following criteria are met:

A. As a follow-up study, when a diagnosis has been established by standard polysomnography, CPAP, BiPAP, or APAP;

B. Oxygen therapy has been initiated;

C. When determining the proper oxygen dose for chronic pulmonary disease;

D. When ordered by a pulmonologist or sleep medicine specialist (The intent is most often to evaluate response to therapy).

VIII. Actigraphy is considered **medically appropriate** when **BOTH** of the following criteria are met:

A. For children aged four (4) to 18 years who have insomnia or circadian rhythm disorder associated with excessive daytime sleepiness; **and**

B. There is a discrepancy between reported sleep history and described symptoms (Only one actigraphy study per year is allowed).

IX. PSG is considered **not medically appropriate** for **ANY** the following indications:

A. Diagnosis of chronic lung disease;

B. Cases of typical uncomplicated and non-injurious parasomnias (e.g., somnambulism, pavor nocturnus, or nocturnal seizures) when the diagnosis is clearly delineated;

C. Epilepsy in individuals who have no specific complaints consistent with a sleep disorder;

D. Diagnosis or treatment of restless leg syndrome, except where uncertainty exists in the diagnosis;

E. Diagnosis of circadian rhythm sleep disorders;

F. Diagnosis of depression;

G. Determining risk of sudden infant death syndrome (SIDS);

H. Diagnosis of bruxism (grinding of teeth);

I. Diagnosis of drug dependency;

J. Insomnia (inability to sleep);

K. Night terrors/dream anxiety;

L. Migraine headaches;

M. Male impotence, other than the allow indications of Policy Statements I.H;

N. Evaluation of for medication-related (titration) sleep stage effects;

O. CPAP titration studies that do not meet criteria for a facility-based PSG (see Policy Statement I.) and CPAP criteria (see Policy Statement IV.);

P. Nocturnal pulse oximetry as a diagnostic tool for any other OSA indication.

X. The following tests are considered **investigational**:

A. EEG topography when used for diagnosis or medical management of OSA syndrome;

B. PAP-Nap;

C. Pharyngometry and Rhinometry Testing for screening, diagnosis, or treatment planning in persons with suspected or known OSA including but not limited to:

1. Acoustic pharyngometry (e.g., Eccovision Acoustic Pharyngometer)
2. Versions of the SNaP Testing System using fewer than three channels;
3. Rhinomanometry;

4. Acoustic rhinometry; **or**
5. Optical rhinometry.

RELATED POLICIES

Corporate Medical Policy

1.01.06 Positive Airway Pressure Devices: CPAP, BPAP, APAP and Noninvasive Positive Pressure Ventilators (NIPPV)

1.01.07 Medical Management Obstructive Sleep Apnea (OSA)

7.01.41 Surgical Management of Sleep Disorders

11.01.03 Experimental or Investigational Services

POLICY GUIDELINE(S)

I. Polysomnography after hypoglossal nerve stimulation implant will require follow up polysomnography specifically related to titration of device.

II. Wrist actigraphy requires a minimum of 14 days of recording, with interpretation of report and results generated. Commercial fitness trackers (e.g., Fitbit) are **ineligible for coverage**.

III. The probability of OSA is determined via a comprehensive sleep evaluation by a sleep specialist. Established sleep disorder tools and questionnaires (e.g., Epworth Sleepiness Scale; Berlin questionnaire, Wisconsin questionnaire, STOP, and STOP-BANG questionnaires) may assist the specialist in the evaluation of an individual with a suspected sleep disorder.

IV. The testing facility must be a sleep disorder center. A sleep disorder center is a medical facility providing clinical diagnostic services and treatment to individuals who present with symptoms or features that suggest the presence of a sleep disorder.

V. The American Academy of Sleep Medicine must accredit all sleep disorder centers, for coverage of the services to be considered.

VI. Sleep studies should be interpreted by a physician who meets any of the following criteria:

   A. Certified by the American Board of Sleep Medicine (ABSM);

   B. Holds subspecialty certification in sleep medicine by a member board of the American Board of Medical Specialties (ABMS), such as the American Board of Family Medicine, the American Board of Internal Medicine, the American Board of Otolaryngology, the American Board of Pediatrics, or the American Board of Psychiatry and Neurology;

   C. Has completed a residency in sleep medicine and meets the Health Plan's credentialing criteria for board certification; or

   D. Is an active staff member of a sleep disorder center certified by the American Academy of Sleep Medicine.

VII. An unattended, cardiorespiratory sleep study (Type III device) may be an acceptable alternative to full night PSG for those individuals with a high-pretest probability of OSA who are without significant comorbid conditions. A full PSG may be required for those symptomatic individuals who have a negative cardiorespiratory home sleep study.

VIII. A home/portable sleep study (HST) is an alternative to a facility-based PSG for individuals who do not meet medically necessary criteria in Policy Statement I.

DESCRIPTION

Sleep disorders medicine is a clinical specialty concerned with diagnosis and treatment of individuals with disorders of sleep and daytime alertness. Categories of sleep disorders include:

Insomnia

Insomnia is a persistent difficulty with sleep initiation, duration, consolidation, or quality that occurs despite adequate opportunity and circumstances for sleep, and results in daytime impairment. Among adults with insomnia, sleep complaints most typically include difficulties initiating or maintaining sleep. Concerns about lengthy periods of nocturnal wakefulness, insufficient amounts of nocturnal sleep, or poor sleep quality often accompany these complaints. Insomnia among children is often reported by their caretakers and characterized by bedtime resistance, frequent nighttime awakenings and/or an inability to sleep independently. Regardless of the exact nature of the nocturnal sleep concerns, daytime impairments are reported, presumably caused by the nighttime sleep difficulties or by some common but unidentified mechanism during sleep and wakefulness. Daytime symptoms typically include fatigue, decreased mood or irritability, general malaise, and cognitive impairment.

Sleep Related Breathing Disorders

Sleep related breathing disorders are characterized by abnormalities of respiration during sleep. In some of these disorders, respiration is also abnormal during wakefulness. The disorders are grouped into OSA disorders, central sleep apnea disorders, sleep related hypoventilation disorders, and sleep-related hypoxemia disorder. However, many individuals will meet diagnostic criteria for more than one of these groups. In particular, many individuals have a combination of obstructive and central sleep apnea. Although a diagnosis is often based on which disorder predominates, this may vary from night to night, as well as over time, in individuals. There is also overlap in pathophysiology, as some central apneas are associated with a closed upper airway and many obstructive apneas begin during a time of falling ventilatory drive.

An individual with a high pre-test probability of moderate to severe obstructive sleep apnea may exhibit the following signs and symptoms, which have been persistent for greater than four weeks in duration. The individual has reported excessive sleepiness or non-restorative, disturbed, or restless sleep and apneas, gasping, or choking at night has been witnessed. The individuals has reported excessive sleepiness or non-restorative, disturbed, or restless sleep and has at least two of the following supporting signs, symptoms, or risk factors: neck circumference greater than or equal to 17 inches for males or 16 inches for females; obesity (BMI greater than 30); physiologic abnormalities compromising respiration (e.g., retrognathia, tonsillar hypertrophy); regularly observed disruptive snoring; refractory hypertension; morning headaches; decreased concentration; memory loss;

decreased libido; irritability; nocturia; individual has unexplained documented pulmonary hypertension; individual has unexplained polycythemia with Hg greater than 18.5 g/dL in males or 16.5 g/dL in females.

Pediatric individuals, aged six years or less, may exhibit the following symptoms: neurobehavioral problems including attention deficit hyperactivity disorder; failure to thrive; neuromuscular disorders; paradoxical breathing; nocturnal diaphoresis; secondary enuresis; or persistent symptoms present for greater than four weeks in duration not only associated with respiratory infections.

Central Disorders of Hypersomnolence

Central disorders of hypersomnolence include a group of disorders in which the primary complaint is daytime sleepiness not caused by disturbed nocturnal sleep or misaligned circadian rhythms. Other sleep disorders may be present, but they must be adequately treated before a diagnosis in this category can be established. The term "hypersomnolence" is used to describe the symptom of excessive sleepiness, whereas "hypersomnia" refers to specific disorders, such as idiopathic hypersomnia.

Circadian Rhythm Sleep-Wake Disorders

Circadian rhythm sleep-wake disorders (CRSWDs) are disorders that are caused by alterations of the circadian time-keeping system or its entrainment mechanisms, or a misalignment of the endogenous circadian rhythm and the external environment. Most CRSWDs arise when a substantial misalignment exists between the internal rhythm and the required timing of the individual's school, work, or social activities. The most common presenting symptoms of CRSWDs are difficulty initiating and maintaining sleep and excessive sleepiness, but their impact extends to adverse health outcomes; impairments in social, occupational, and educational performance; and safety concerns.

Parasomnias

Parasomnias are undesirable physical events or experiences that occur during entry into sleep, within sleep, or during arousal from sleep. Parasomnias may occur during non-rapid eye movement sleep (NREM), rapid eye movement sleep (REM), or transitions to and from sleep. Parasomnias encompass abnormal, sleep-related, complex movements, behaviors, emotions, perceptions, dreams, and autonomic nervous system activity. Parasomnias are clinical disorders because of the resulting injuries, sleep disruption, adverse health effects, and untoward psychosocial effects. The clinical consequences of the parasomnias can affect the individual, the bed partner, or both.

Sleep Related Movement Disorders

Sleep-related movement disorders are primarily characterized by simple, usually stereotyped, movements that disturb sleep or its onset. Restless leg syndrome (RLS) is an exception in that individual typically engage in walking or non-stereotypic limb movement to reduce leg discomfort. However, RLS is closely associated with periodic limb movements (PLMs), which are usually simple and stereotyped within a series. Nocturnal sleep disturbance or complaints of daytime sleepiness or fatigue are a prerequisite for a diagnosis of a sleep-related movement disorder. Body movements that disturb sleep also are seen in many other sleep disorder categories (e.g., parasomnias such as sleepwalking, sleep terrors, and REM sleep behavior disorder). However, these parasomnias differ

from the simple stereotyped movements categorized as sleep-related movement disorders in that they involve complex behaviors during the sleep period. Parasomnia-related movements may appear purposeful and goal-directed but are outside the conscious awareness of the individual. Parasomnias are listed in a separate section from the sleep-related movement disorders.

Types of Sleep Assessments

A polysomnography, or PSG, refers to any one of a class of tests that utilizing continuous polygraph recording, usually over the course of a night, of electrophysiological measurements relevant to diagnosing sleep disorders. The four components of a PSG include: (1) electrographic recordings (EKG, EMG, EEG, EOG); (2) ventilatory variables that permit the identification of apneas and their classification as central or obstructive; (3) arterial oxygen saturation by finger oximetry; and (4) heart rate. In addition, a PSG may also include additional monitoring modalities such as esophageal monitoring and blood pressure monitoring. By definition, a PSG always requires sleep staging (EEG, EOG, and EMG).

In contrast, an unattended cardiorespiratory sleep study does not include sleep staging. The components of any sleep test are dictated by the clinical situation. The number and nature of parameters studied depends upon the judgment of the sleep disorders medical specialist. The terms "sleep studies" and "polysomnogram" are often used interchangeably. However, CPT and HCPCS coding makes the distinction between the two in the following way: polysomnography includes EEG monitoring, while unattended cardiorespiratory sleep studies do not.

An at home sleep apnea test (HSAT) is an alternative to an attended PSG for OSA diagnosis. The test is performed in the individual home, unsupervised by a sleep technician and usually consist of a recording device and related accessories. Home sleep apnea test measures fewer parameters than attended sleep study. Depending on the type of home device, it can monitor and track breathing efforts, detect snoring, oxygen level, and body movements. Most HSAT measure airflow, breathing efforts, blood oxygen levels and heart rate and produce an estimate of severity (i.e., respiratory event index (REI) based on monitoring time. The conventional sensors used in HSAT devices are unable to detect hypopneas and may underestimate the severity of OSA.

Sleep studies have been categorized as Type I, Type II, Type III, or Type IV. Unattended studies fall into categories Type II through Type IV. Type II studies use the same monitoring sensors as full PSGs (Type I) but are unattended and can be performed outside of the sleep laboratory. Type III studies are conducted with portable monitors that have at least two respiratory channels in addition to measuring oxygen saturation and heart rate. Some Type III devices may offer extra measurements, such as detection of snoring and movement. Type IV studies utilize devices that measure only 1 or 2 parameters, typically oxygen saturation and heart rate, or in some cases, just air flow.

Split-night sleep studies utilize the final portion of the overnight PSG to titrate CPAP. A split-night sleep study is an alternative to a full night of diagnostic PSG followed by a second night of CPAP titration.

Multiple Sleep Latency Test (MSLT) is performed the day after overnight PSG is completed. MSLT utilizes the same parameters as a basic polysomnogram for sleep staging (e.g., EEG, EKG, EMG,

EOG). It measures mean sleep latency (MSL), calculated by the average time elapsed from the start of daytime nap periods to the onset of sleep. The standardized MSLT is conducted with four or five nap attempts during a single day, which are each separated by two hours. Each nap attempt is ended if the subject fails to fall asleep within 20 minutes. An MSL of eight minutes or less and two or more sleep onset REM periods on the MSLT is indicative of a pathological state called narcolepsy (Iskander et al., 2023).

Pharyngometer and rhinometer testing, the pharyngometer graphically displays the relationship between the cross-sectional area of the airway and the distance down the airway in centimeters. The rhinometer uses acoustic reflection to map out the cross-sectional area measurements into the nasal airway.

EEG Topography is a computer based electroencephalographic mapping of the spatial distributions of pre-defined frequency bands.

Nocturnal pulse oximetry is the measurement of oxygen saturation, usually overnight, in the home. It is utilized for several clinical purposes such as evaluating individuals for obstructive sleep apnea and for determining oxygen dosing in individuals with chronic pulmonary disease.

Actigraphy consists of a small portable device, usually worn on the wrist or ankle, that senses physical motion and stores that information for future displaying, scoring, and interpretation. Recordings can be conducted for days or weeks on individuals in their own homes. Actigraphy has been used by researchers to measure sleep disturbances reflective of a variety of clinical sleep disorders, including insomnias, hypersomnia, circadian rhythm disorders, and PLM disorders.

PAP-Nap (Positive Airway Pressure Nap) is an abbreviated daytime sleep evaluation that has been proposed as a method of assessing, addressing and alleviating physical, mental, and emotional barriers in individuals who may benefit from PAP therapy. PAP-NAPs include mask and pressure desensitization, emotion-focused therapy to overcome aversive emotional reactions, mental imagery to divert individual attention from mask or pressure sensations, and physiological exposure to PAP therapy during a 100-minute nap period. The primary goal of PAP-Nap is to help individuals use PAP therapy for more than one hour, during which they have the potential to fall asleep with the mask in place or at least report that the experience was comfortable. PAP-Nap is not a titration but instead provides the individual with physiologic exposure to PAP therapy as well as to the lab environment. It does not provide definitive sleep or breathing evaluations.

SUPPORTIVE LITERATURE

Overnight PSG is an established diagnostic procedure used in conjunction with clinical examination in determining the presence and extent of OSA. PSG is considered the "gold standard" of OSA diagnosis and follow-up. It provides objective data on the type and severity of sleep-disordered breathing.

Pulse oximetry, when used alone, has not shown to have an adequate negative predictive value to rule out OSA (all individuals with symptoms of OSA would require PSG regardless of whether pulse oximetry was negative or positive). Overnight oximetry has not been demonstrated to be a sufficiently reliable predictor of the presence of OSA, particularly mild OSA.

Actigraphy has been used in many research studies for the evaluation of rest-activity cycles. This technique has not been validated as a method of diagnosing OSA. The major limitation of the methodology is precision, as well as the lack of correlation between physical movement and sleep architecture. The role of actigraphy in clinical management of OSA is not clear, but it can be helpful in determining the length of time in bed and activity levels. Actigraphy studies show that it is not a sufficiently accurate substitute measure for sleep time, to recommend for routine use. The default actigraphy settings may not be optimal for people with COPD and coexisting insomnia. The American Academy of Sleep Medicine (AASM) 2018 guidelines considered the use of actigraphy "conditional" (low degree of certainty of the outcome and appropriateness of the patient-care strategy) for all indications including insomnia (adult and pediatric) and circadian rhythm sleep-wake disorder, and to estimate or monitor total sleep time for patients with sleep-disordered breathing. The AASM indicated that actigraphy should not be used in place of electromyography for the diagnosis of periodic limb movement (PLM) disorder in either adults or pediatric patients.

MSLT is a validated, objective measure of the tendency to fall asleep and the ability to stay awake for a defined time, respectively. Studies of the MSLT procedure demonstrate significant differences in mean sleep latency values between healthy subjects and patients with excessive sleepiness due to narcolepsy or idiopathic hypersomnia.

There is insufficient evidence in the published medical literature to determine whether PAP-Nap studies result in improved adherence to therapy of improved patient outcomes.

The diagnosis of PLM disorder requires quantification of PLMs and PLM-related arousals, assessment of the impact of the movements upon sleep architecture, and identification and exclusion of other sleep disorders. Although PLM disorder can exist independent of restless leg syndrome (RLS), it is estimated that over 80% of individuals with RLS have evidence of PML on PSG, so PSG may be helpful in increasing the confidence in the RLS diagnosis.

Pharyngometer and rhinometer testing for screening, diagnosis, or treatment planning in persons with suspected or known OSA and for all other indications lacks clinical studies demonstrating that these tests improve clinical outcomes, and their effectiveness has not been established. The methods that detect structural and functional abnormalities of the upper airway implicated as risk factors for OSA continue to stimulate interest, because it is hoped that they may allow physicians to distinguish patients more easily with OSA from those without it, and, thereby, reduce the number of unnecessary sleep studies. The evidence of efficacy necessary to support the correlation between test results and OSA diagnosis is lacking.

PROFESSIONAL GUIDELINE(S)

The American Academy of Sleep Medicine issued recommendation in 2017 that were intended as a guide for clinicians diagnosing OSA in adults. A STRONG recommendation was one that clinicians should follow under most circumstances. A WEAK recommendation reflected a lower degree of certainty regarding the outcome and appropriateness of the patient-care strategy for all individuals. The AASM indicated that the ultimate judgment regarding the propriety of any specific care must be made by the clinician in light of the individual circumstances presented by the individuals, available diagnostic tools, accessible treatment options, and resources.

The AASM considered the following to be good practice statements:

- Diagnostic testing for OSA should be performed in conjunction with a comprehensive sleep evaluation and adequate follow-up.
- Polysomnography is the standard diagnostic test for the diagnosis of OSA in adult individuals in whom there is a concern for OSA based on a comprehensive sleep evaluation.

The AASM 2017 recommendations include:

- Clinical tools, questionnaires and prediction algorithms should not be used to diagnose OSA in adults, in the absence of polysomnography or home sleep apnea testing. (STRONG)
- Polysomnography, or home sleep apnea testing with a technically adequate device, should be used for the diagnosis of OSA in uncomplicated adult individuals presenting with signs and symptoms that indicate an increased risk of moderate-to-severe OSA. (STRONG)
- If a single home sleep apnea test is negative, inconclusive, or technically inadequate, polysomnography should be performed for the diagnosis of OSA. (STRONG)
- Polysomnography, rather than home sleep apnea testing, should be used for the diagnosis of OSA in individuals with significant cardiorespiratory disease, potential respiratory muscle weakness due to neuromuscular condition, awake hypoventilation or suspicion of sleep-related hypoventilation, chronic opioid medication use, history of stroke or severe insomnia. (STRONG)
- If clinically appropriate, a split-night diagnostic protocol, rather than a full-night diagnostic protocol for polysomnography should be used for the diagnosis of OSA. (WEAK)
- When the initial polysomnogram is negative and clinical suspicion for OSA remains, a second polysomnogram should be considered for the diagnosis of OSA. (WEAK)
- The AASM Position Statement for the Use of Home Sleep Apnea Test (HSAT) for Diagnosis of OSA in Children states that the use of a home sleep apnea test is not recommended for the diagnosis of OSA in children.

According to the American Association of Sleep Technologists (2020), and the AASM (2017) a technically adequate HSAT device incorporates a minimum of the following sensors: nasal pressure, chest and abdominal respiratory inductance plethysmography, and oximetry; or peripheral arterial tonometry (PAT) with oximetry and actigraphy (2). The technical requirements for these channel types should meet the standards outlined in the current AASM Manual for the Scoring of Sleep and Associated Events (3). A single HSAT recording should be conducted over at least one night. If a HSAT result is negative, inconclusive or technically inadequate, polysomnography should be performed to rule out the diagnosis of OSA.

In 2021, the AASM published a guidance statement that focused on indications for follow-up sleep apnea testing with PSG or home sleep apnea tests in individuals with OSA. The following clinical guidance statements were provided:

- Follow-up PSG or HSAT is not recommended for routine reassessment of asymptomatic individuals with obstructive sleep apnea on PAP therapy, however, follow-up PSG or HSAT can be used to reassess individuals with recurrent or persistent symptoms, despite good PAP adherence;
- Follow-up PSG or HSAT is recommended to assess response to treatment with non-PAP interventions;
- Follow-up PSG or HSAT may be used if clinically significant weight gain or loss has occurred since diagnosis of OSA or initiation of its treatment;
- Follow-up PSG may be used for reassessment of sleep-related hypoxemia and/or sleep-related hypoventilation following initiation of treatment for OSA;
- Follow-up PSG or HSAT may be used in individuals being treated for OSA who develop or have a change in cardiovascular disease;
- Follow-up PSG may be used in individuals with unexplained PAP device-generated data.

REGULATORY STATUS

The United States Food and Drug Administration (FDA) regulates sleep study devices as medical devices. All sleep study devices including related components require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2025 Dec 15]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most serious type of recalls. Available from: Medical Device Recalls | FDA [accessed 2025 Dec 15]

The United States Food and Drug Administration (FDA) has approved several home sleep devices to diagnosis sleep related breathing disorders. The Somfit system is a non-invasive prescription device intended for home use with individuals suspected to have sleep-related breathing disorders. It collects physiological data and is comprised of a single-use adhesive-gel electrode worn on the individual forehead, an app and a cloud-based data management and reporting system. The device calculates and reports to clinicians EEG/EOG channels, sleep stages, oxygen saturation, peripheral arterial tonometry signal, pulse rate, and snoring level. The Sleep Doctor is another FDA approved home sleep device that utilizes finger, wrist, and chest sensors to monitor seven metrics associated with sleep apnea quality.

CODE(S)

MEDICAL POLICY

Medical Policy Title	**Small Bowel and Multivisceral Transplants in Adults and Children**
Policy Number	**07.02.05**
Current Effective Date	**July 1, 2026**
Next Review Date	**March 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Candidates for Small Bowel (SB) or Multivisceral (MV) transplant must meet **ALL** of the following criteria:

A. Adequate cardiopulmonary status;

B. Absence of active infection;

C. Absence of malignancy (other than non-melanoma skin cancers), unless malignancy has been completely resected, or (upon medical review) it is determined that malignancy has been treated with small likelihood of recurrence and acceptable future risks;

D. Documentation of patient compliance with medical management; **and**

E. Meet **ALL** of the transplant specific criteria:

Small Bowel Transplant

1. Small bowel (SB) transplantation is considered **medically appropriate** in pediatric and adult patients with short bowel syndrome (SBS) for **ANY** of the following indications:

a. Impending or overt liver failure due to total parenteral nutrition (TPN)-induced liver injury;

b. Thrombosis of two (2) or more central veins;

c. Two (2) or more episodes per year of systemic sepsis secondary to line infection that require hospitalization;

d. A single episode of line-related fungemia, septic shock, or acute respiratory distress syndrome; **or**

e. Frequent episodes of severe dehydration, despite intravenous fluid supplementation in addition to TPN;

2. SB transplant is considered **investigational** for **BOTH** of the following:

a. Being considered for adult or pediatric individuals with intestinal failure who can

tolerate TPN; **and**

b. SB transplant using live donor tissue.

Multivisceral Transplant

3. Multivisceral (MV) transplantation is considered **medically appropriate** in pediatric and adult patients with intestinal failure **AND** concurrent liver failure.

POLICY GUIDELINE(S)

I. Pre-transplant evaluation documentation should include the following clinical information (if testing is unable to be performed, the rationale for not performing the testing should be included in the documentation):

A. Clinical Evaluation:

1. Confirmation of diagnosis;
2. Identification of comorbidities;
3. Current assessment of co-morbidities;
4. Management of co-morbidities; **and**
5. Consult notes (if applicable);

B. Psycho-Social Evaluation:

1. Identification of stressors (e.g., family support, noncompliance issues, motivational issues, alcohol, or smoking/substance abuse);

C. Performance Status:

1. Karnofsky performance score;
2. Palliative Performance Scale (PPS) score;
3. Eastern Cooperative Oncology Group (ECOG) performance status; **or**
4. Lansky Play-Performance Scale (for age 1 to 16 years);

D. Oral Health Evaluation;

E. Lab Tests:

1. CBC, metabolic profile;

2. Serologies: CMV, Hepatitis B and C; **and**
3. HIV Testing;

F. Cardiac Assessment:
1. 12 Lead EKG;
2. Stress (exercise, nuclear, or dobutamine), **and**
3. Echo or MUGA Scan;

G. Pulmonary Assessment:
1. Chest X-ray;
2. Pulmonary function tests (PFTs); for high-risk for respiratory failure (COPD, emphysema, alpha-1-antritrypsin deficiency, hepatopulmonary syndrome, or significant smoking history); **and**

H. Age-Appropriate Screening Tests: Please refer to the U.S Preventive Services Task Force (USPSTF) website for list of age-appropriate screening guidelines. [accessed 2026 Jan 30]. Available from: https://uspreventiveservicestaskforce.org/uspstf/

II. Small Bowel and Multivisceral Transplants are considered a relative contraindication in human immunodeficiency virus (HIV) positive recipients, unless **ALL** of the following criteria are met:

A. Patient's CD4 count is greater than 200 cells/mm3;

B. HIV-1RNA is undetectable;

C. Patient has been on stable anti-retroviral therapy for greater than three (3) months;

D. Patient has no other complications from AIDS (e.g., opportunistic infection, including aspergillus, tuberculosis, coccidioidomycosis; resistant fungal infections, Kaposi's sarcoma, or other neoplasm); and

E. Patient meets all other criteria for transplantation.

DESCRIPTION

Small Bowel Transplant

The purpose of a small bowel (SB) transplant is to restore bowel function and allow for adequate nutrition in patients with short bowel syndrome (SBS). It may be an alternative to total parenteral nutrition (TPN) for selected patients who are predicted to have poor survival on TPN. SBS is a condition in which the absorbing surface of the small intestine is inadequate due to extensive disease or surgical removal. The spectrum of clinical disease varies widely, from only single micronutrient malabsorption to complete intestinal failure, defined as the reduction of gut function below the minimum necessary for the absorption of macronutrients and/or water and electrolytes.

In adults, etiologies of short bowel syndrome include ischemia, trauma, volvulus, and tumors. In children, gastroschisis, volvulus, necrotizing enterocolitis, and congenital atresia are predominant

causes. The actual prevalence of short bowel syndrome is not clear primarily due to under-reporting and a lack of reliable patient databases.

Multivisceral Transplant (MV)

MV is the most extensive form of intestinal transplant, and an infrequently performed procedure, but, without it, most candidates, candidates will likely face 100% mortality. MV includes the simultaneous transplant of multiple abdominal organs that are reliant on the celiac axis and superior mesenteric artery, including the stomach, duodenum, pancreas, and small intestine, with or without the liver (modified multivisceral transplant). Some centers may also include the colon or elect to simultaneously remove the spleen. Organs selected in addition to the small intestine are dependent upon the patient's specific disease.

Candidates for MV transplant have SBS and terminal liver failure or other gastrointestinal problems, such as pancreatic failure, thromboses of the celiac axis and the mesenteric artery, or pseudo-obstruction affecting the entire gastrointestinal tract.

Total parenteral nutrition (TPN) is the only established treatment that can produce long-term survival, once the small intestine is dysfunctional, and oral nutrition is ineffective. TPN requires placement of a permanent venous access device. There are some serious, life-threatening complications that can occur as a result of TPN, including hepatobiliary disease, thrombosis due to the venous catheter, or sepsis from the venous access line.

SUPPORTIVE LITERATURE

There are limited long-term data on SB and MV transplants, due to the small numbers of transplantations performed. Intestinal transplants (including multivisceral and bowel/liver) represent a small minority of all solid organ transplants. In 2024, 80 intestinal transplants were performed in the U.S. according to the U.S. Department of Health and Human Services (DHHS) Organ Procurement and Transplantation Network National Data 2024. The number of new patients added to the intestinal transplant waiting list as of January 30, 2026, was 200.

Sudan (2010) published a review of the literature on long-term outcomes after intestinal transplantation. Sudan noted that intestinal transplantation had become standard therapy for patients with life-threatening complications from parenteral nutrition therapy. Data from current single center series have indicated 1-year patient survival rates between 78% and 85% and 5-year or more survival rates between 56% and 61%.

Pediatric intestinal transplant patients, most achieve normal growth velocity at 2 years posttransplant. However, oral aversion is common; tube feedings are necessary for 45% of children. Sudan also reported on parental surveys of quality of life for pediatric transplant patients in which intestinal transplant patients appear to have modestly improved quality of life compared with those remaining on TPN and slightly worse than matched school-age controls without intestinal disease.

In 2022, Roberts et al conducted a multicenter international cohort study to validate the Toronto criteria (Burghadt et al 2015), a set of pediatric criteria for intestinal transplantation which included 1) two or more intensive care unit admissions requiring ventilatory or inotropic support, 2) loss of

three or more out of six central venous catheter sites, and 3) persistent elevation of conjugated bilirubin (≥ 75µmol/L) following six weeks of lipid management strategies. The Toronto criteria was based on the experiences of a single center. Roberts and colleagues aimed to prove that the data could be generalized to all pediatric patients with intestinal failure by reviewing a cohort of 443 patients who were included in the study if they were less than 18 years of age at the time of diagnosis, and with intestinal failure due to a primary gastrointestinal disorder (e.g., short bowel syndrome, motility disorder or congenital diarrhea, and enteropathy). Excluded were patients with a malignancy, metabolic, or mitochondrial disease, or any other independently life-limiting condition. Follow-up was one year, at a minimum. Patient data was collected from hospital records and included patient status at the end of the study (alive, dead or transplanted) for each of the proposed listing criteria, which was similar to the Burghadt criteria but did extend the length of lipid strategies to 8 weeks and also separated central venous catheter sites into upper and lower body sites, and upper body sites only. Validation of the criteria was done by calculating the sensitivity, specificity, negative predictive value (NPV), positive predictive value (PPV), and probability of death or transplant for each of the criteria. Median age at the diagnosis of intestinal failure was 0.1 years (Interquartile ratio (IQR) 0.03-0.14) with median follow up of 3.8 years (IQR 2.3-5.3). A total of 9% (40/443) of patients died, 12 % (53/443) were transplanted. A total of 11 patients died post-transplant. The criteria had a high predictive value of death and intestinal transplantation ($p<.0001$, 95% Confidence Interval). Authors concluded that although the study was of lower statistical power, the outcomes confirm the results of the single center cohort, thereby confirming the validity of the three proposed Toronto listing criteria for intestinal transplant in children.

Living donor isolated or combined liver/intestinal transplants have been studied in very small case studies. Typically, living donor transplants have been reserved for children who are at high risk for premature death while on the cadaveric waiting list and who have no central venous access, or for children with impending TPN-related liver failure (Gangemi 2009). A living donor liver transplant may be performed first, followed by an intestinal transplant from the same donor later. Advantages to living donors' transplants include better human leukocyte antigen (HLA) matching, reduction of cold ischemia time, and no waitlisting for a transplant; thus, the patient is less likely to die while waiting for an organ. Results from the studies showed few or no complications for the donor after transplant. Most complications for the recipient, such as diarrhea, weight loss, and nausea, were resolved within a few weeks of surgery. However, these small studies are lacking long-term follow-up of the donors.

Patient survival and graft survival for recipients of living donor combined liver/intestinal or isolated intestinal transplants has been favorable. More large studies are needed, to determine whether patient survival rate is comparable to or better than the survival rate for patients receiving cadaveric organs. Most studies suggest that living donor-transplanted organs are to be reserved for circumstances in which there is high risk for death, and no cadaveric donors are available.

PROFESSIONAL GUIDELINE(S)

In 2001, the American Society of Transplantation issued a position paper on indications for pediatric intestinal transplantation (Iyer 2022). The Society listed the following disorders in children as being potentially treatable by intestinal transplantation: short bowel syndrome, defective intestinal motility,

and impaired enterocyte absorptive capacity. Contraindications for intestinal transplants to treat pediatric patients with intestinal failure are similar to those of other solid organ transplants: profound neurologic disabilities, life-threatening comorbidities, severe immunologic deficiencies, nonresectable malignancies, autoimmune diseases, and insufficient vascular patency.

In 2022, the American Gastroenterological Association (AGA) (Iyer 2022) published a clinical practice update on the management of short bowel syndrome. The guidance recommends referral for intestinal transplantation for "patients with intestinal failure (i.e., refractory parenteral nutrition dependency) and onset of parenteral nutrition failure, especially the occurrence of progressive intestinal failure-associated liver disease or catheter related complications such as recurrent catheter-related sepsis or loss of vascular access due to thrombosis of the central veins." The guidance stresses wider adoption of pre-emptive intestinal transplant, before parenteral nutrition complications are an issue, including such patients who do not meet the strict historical criteria of parenteral nutrition failure (e.g., severe dysmotility syndromes who are not anticipated to ever wean from PN, and those with large abdominal desmoid tumors). Regarding the use of intestinal transplantation in pediatric patients, authors noted that the document focus is on adult patients, "however, some overlap with the management of pediatric short bowel syndrome may be present".

In 2001, the United Network for Organ Sharing (UNOS) indicated that asymptomatic HIV-positive patients should not necessarily be excluded from candidacy for organ transplantation, stating, "A potential candidate for organ transplantation whose test for HIV is positive but who is in an asymptomatic state should not necessarily be excluded from candidacy for organ transplantation, but should be advised that he or she may be at increased risk of morbidity and mortality because of immunosuppressive therapy."

In 2013, the American Association for the Study of Liver Diseases and the American Society of Transplantation published practice guidelines related to the evaluation of liver transplantation in adults. More than 50 recommendations were included, the strength of the recommendations were classified as strong, or weak and the quality of evidence was rated as high (A), moderate (B), or Low (C). Level 1-A recommendations include the following:

- "Evaluation for LT should be considered once a patient with cirrhosis has experienced an index complication such as ascites, hepatic encephalopathy, or variceal hemorrhage or hepatocellular dysfunction results in a MELD Score ≥ 15.
- Potential recipients with portopulmonary hypertension (POPH) should be evaluated by a pulmonary or cardiac specialist for vasodilator therapy.
- HPS is relatively common in patients evaluated for LT and should be screened by pulse oximetry.
- Renal dysfunction requires vigorous evaluation prior to LT to determine etiology and prognosis.
- Tobacco consumption should be prohibited in LT candidates.
- Candidates should undergo age and risk factor-appropriate cancer screening, e.g., colono-scopy, mammography, Papanicolaou smear.
- LT candidates should be screened for bacterial, viral, and fungal infections prior to LT.

- Vaccination should be encouraged against pneumococcus, influenza, diphtheria, pertussis, and tetanus.
- Bone densitometry should be obtained as part of transplant evaluation and treatment of osteoporosis initiated prior to LT.
- Nutritional assessment should be performed in every LT candidate.
- Patients with HIV infection are candidates for LT if immune function is adequate and the virus is expected to be undetectable by the time of LT.
- Patients should be evaluated for and meet reasonable expectations for adherence to medical directives and mental health stability as determined by the psychosocial evaluation.
- LT transplant candidates with HCV have the same indications for LT as for other etiologies of cirrhosis.
- Patients with HBV (hepatitis B) liver disease should receive antiviral therapy to suppress HBV replication pre-transplant and continued surveillance for HCC.
- LT is indicated for decompensated primary biliary cirrhosis (PBC).
- LT should be considered in patients with decompensated autoimmune hepatitis who do not respond to or are not appropriate candidates for medical therapies.
- LT is an effective therapy for decompensated liver disease due to primary sclerosing cholangitis (PSC), including bouts of recurrent cholangitis and sepsis.
- Early referral of ALD patients for initiation of LT evaluation facilitates psychosocial assessment and setting addiction treatment goals.
- Patients with acute liver failure (ALF) require immediate referral to a liver transplant center.
- Patients with acetaminophen overdose should be evaluated for and meet reasonable expectations for adherence to medical directives and mental health stability as determined by the psychosocial evaluation.
- LT is an effective therapy for Hepatocellular carcinoma (HCC) within the Milan criteria.
- LT is an effective therapy for decompensated liver disease due to non-alcoholic steatohepatitis (NASH) or cryptogenic cirrhosis.
- LT is indicated for decompensated cirrhosis due to a-1-antritrypsin deficiency.
- Screening to exclude lung disease with pulmonary function tests and chest imaging should be undertaken in patients with a-1-antritrypsin deficiency being evaluated for LT.
- Urgent LT is indicated for Wilsonian acute liver failure.
- LT is indicated in decompensated cirrhosis due to Wilson's disease unresponsive to medical therapy.
- LT is indicated for decompensated cirrhosis due to hemochromatosis.

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

- Preemptive LT (prior to the development of advanced renal disease) or combined liver and kidney transplantation in the setting of ESRD are curative for primary hyperoxaluria and should be considered for patients who do not respond to medical therapy."

In 2014, the North American Society of Transplantation and the North American Society for Pediatric Gastroenterology, Hepatology & Nutrition published AASLD practice guidelines for the evaluation of the pediatric patient for liver transplant (LT) (with liver transplant included within the definition of multivisceral transplants). Over 90 recommendations were included, the strength of the recommendations were classified as strong, or weak and the quality of evidence was rated as high (A), moderate (B), or Low (C), including, but not limited to, the following:

- "A multidisciplinary pediatric LT evaluation team should be skilled in pediatric conditions and properly communicate with the family and the child, when appropriate, the processes, risks, and benefits associated with LT. (2-B)
- Immediate contact with pediatric LT center should be initiated for children with acute liver failure or acute decompensation of an established liver disease; emergent referral for LT evaluation may be required. (1-A)
- Children with liver-based metabolic crises refractory to medical and/or surgical therapy (1-B), unresectable hepatoblastoma (1-B), or evidence of hepatocellular unresectable carcinoma (1-B) should be referred urgently for LT evaluation.
- Biliary atresia (BA) patients who are post-hepatoportoenterostomy (HPE) should be promptly referred for LT evaluation if the total bilirubin is greater than 6mg/dL beyond 3 months from HPE. (1-B); liver transplant evaluation should be considered in BA patients whose total bilirubin remains between 2-6 mg/dL. (1-B)
- Referral for LT evaluation should be anticipated for children with chronic liver disease and evidence of deteriorating liver function characterized by poor weight gain, growth failure, variceal hemorrhage, intractable ascites, recurrent cholangitis, or episodes of spontaneous bacterial peritonitis, pruritus, advancing encephalopathy, and/or uncorrectable coagulopathy (1-B).
- A review of the local records by the LT team prior to LT evaluation will inform the evaluation schedule and enable affirmation of the primary diagnosis, assessment of comorbidities, and identify technical challenges related to LT. (2-B)
- In collaboration with the local primary pediatric specialist, management of the primary disease and comorbidities should be reviewed and optimized. (2-B)
- Aggressive nutritional support for children awaiting LT should be initiated to optimize outcomes (1-B); NG tube feedings and parenteral nutrition may be needed in some circumstances. (2-B)
- Two-dimensional echocardiography (2-DE) with Doppler should be performed in all patients at the time of liver transplant evaluation (2-B); if the right ventricular systolic pressure is over 50 mmHg by 2-D echo, a right-heart cardiac catheterization is necessary to establish the diagnosis of portopulmonary hypertension. (2-B)

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

- Pulmonary function tests, including forced expiratory volume in one second and forced vital capacity should be performed in patients with cystic fibrosis evaluated for liver transplant. (2-B)
- Renal function should be assessed in all patients, with special emphasis on those with metabolic liver diseases associated with renal dysfunction (1-B) and those at increased risk for calcineurin inhibitor toxicity. (2-B)
- Serum creatinine alone should not be used to assess renal function (1-B); either cystatin C (2-B) or the revised Schwartz Formula (2-C) should be used to estimate the glomerular filtration rate in children with chronic liver disease.
- Children with end stage liver disease should receive a careful oral examination looking for evidence of dental caries, gingival disease, or dental abscess - referral to a pediatric dentist should occur if abnormalities are identified. (2-B)
- Completion of all age-appropriate vaccinations, for the child and family members, should occur prior to transplantation and ideally before the development of end-stage liver disease (1-B); children who have not completed the necessary vaccine schedule can receive vaccinations on an accelerated schedule. (1-B)
- Evidence of a prior Epstein-Barr virus and cytomegalovirus infection, as determined by virus-specific serological measurements, should be per-formed on all individuals evaluated for liver trans-plant, recognizing that for children less than 12-18 months of age, antibodies may have been passively transmitted to the child from the mother. (I-A)
- Families should be assessed to ensure social services and psychosocial support systems are adequate for LT-candidates in order to optimize post transplantation outcomes. (1-B)
- Patients and families at potential risk for nonadherence should be identified and receive focused psychosocial interventions prior to and following transplantation. (1-B)
- Neurocognitive testing should be performed in children awaiting LT to identify areas warranting early intervention to minimize later cognitive difficulties (2-B).
- BA patients post-HPE should be promptly referred for LT evaluation if the total bilirubin is greater than 6 mg/dL beyond 3 months from HPE (1-B); liver transplant evaluation should be considered in BA patients whose total bilirubin remains between 2-6 mg/dL (1-B), and for those with lesser bilirubin values who have unmanageable consequences of biliary cirrhosis or portal hypertension. (2-B)
- Careful assessment of cardiac and renal function should occur during LT evaluation in all liver transplant candidates. (2-B)
- Pretransplant vascular imaging of the intra-abdominal vasculature should be performed (2-B); vascular imaging of the head and neck may be considered. (2-C)”

REGULATORY STATUS

Organ transplants, as surgical procedures, do not require U.S. Food and Drug Administration (FDA) approval. The Health Resources Services Administration (HRSA) oversees the transplantation of vascularized human organs through the Organ Procurement and Transplantation Network (OPTN). For more information view the OPTN: https://www.hrsa.gov/optn [accessed 2026 February 23].

The HIV Organ Policy Equity (HOPE) Act was signed into law on November 21, 2013, and the provisions of the Act took effect on November 21,2015. The HOPE act permits donated, HIV-positive kidney and liver organs to be used for transplantation in HIV-positive patients. The HOPE Act directs the Department of Health and Human Services and the Organ Procurement Transplant Network (OPTN) to develop and institute standards for research on HIV-positive organ transplantation and permits the Secretary to permit positive-to-positive transplantation if it is determined that the results of research warrant such a change. The Secretary would be required to direct OPTN to develop standards to ensure that positive-to-positive transplantation does not impact the safety of the organ transplantation network. In addition, the Act amends federal criminal law regarding HIV transmission to clarify that such organ donations are not barred. In May of 2020, the HOPE Act was amended to include organs of any type.

CODE(S)

DESCRIPTION

Remote Electrical Neuromodulation (REN)

REN is a nonpharmacologic abortive treatment for migraines. The Nerivio device (Theranica) was cleared by the FDA for patients aged 12 years and above. It is a wireless stimulation device applied to the lateral upper arm in 45-minute sessions and triggers weak electrical impulses to start conditioned pain modulation, a proprietary electrical signal to stimulate noxious sensory fibers and relieve acute migraine. It is controlled by a mobile app that includes a migraine diary to track

migraine headaches and treatment sessions. Each device functions for 12 treatments, after which, it is to-be disposed of and a new device is required.

Afferent Patterned Stimulation Therapy for Essential Tremor

The Cala Trio (Cala Health) is an external upper limb stimulator. It is a hand-specific device indicated to relieve tremors in adults with essential tremor. The device is worn like a wristwatch. Electrodes embedded into a disposable cloth band deliver stimulation to the median and radial nerves of the wrist after being calibrated to the specific motion of the user. The digital display provides prompts, time, offers the ability to adjust intensity and notifies the user when the band requires changing. The contained accelerometer measures the tremor and adjusts simulation. Sessions are for 40-minutes, and the device is recommended to be used twice daily prior to activities requiring use of that hand.

SUPPORTIVE LITERATURE

Remote Electrical Neuromodulation

Yarnitsky et al (2019) conducted a vendor- funded double blind RCT from involving 252 patients at 12 different sites who met the international classification of headache disorders criteria for migraine, had two to eight migraines per month and less than 12 headache days per year. The authors aimed to evaluate the efficacy and safety of REN for the acute treatment of migraine. Treatment sessions with the device were 45 minutes. Pain relief was defined as improvement from severe or moderate pain to mild or none, or improvement from mild pain to none, of which 66.7% of the active treatment group achieved pain relief at 2 hours post-treatment compared to 38% in sham group. Sustained relief (48 hours post treatment) was achieved by 39% of the treatment group, and 16% of the sham group. Adverse events were mild and rare. The authors report that the findings are equivalent to migraine relief found with triptan use. The approval of Nerivio for adolescents was based on a study by Hershey et al (2020), a vendor-funded single-arm multicenter study of 39 patients with migraine between the ages of from the ages of 12 and 17. Pain relief at 2 hours was achieved by 71% (28/39) of the patients, and 35% (14/39) were pain free within 2 hours. Study enrollment was shortened to 60% of the planned target due to the coronavirus pandemic however since pain relief at 2 hours was achieved by more than 60% it was determined to be complete. Of those that had pain relief and pain freedom, 90% had sustained relief or freedom for 24 hours. Additional symptoms of nausea, photophobia and phonophobia disappeared at 2 hours in 54%, 41% and 40% of treated individuals. There were mild and low device related adverse events for both of the studies. The writers concluded that Nerivio is both safe and effective for the treatment of acute migraine in adolescents. Longer and larger RCTs with relevant comparators are needed to determine if results can be replicated in other populations, and if the treatment is superior to the current standard of care.

Afferent Pattern Stimulation

Pahwa et al (2019) studied the use of a novel peripheral (radial and median nerves) stimulation device for the treatment of essential tremor via a RCT of 77 patients and compared to sham stimulation. Although the primary endpoint (an improvement in the Tremor Research Group Essential Tremor Rating Assessment Scale (TETRAS) Archimedes spiral scores) was not met, the authors noted significant improvements in some subject-rated tasks in activities of daily living and clinical global

impression-improvement (CGI-I) rating after stimulation. The outcomes were similar to the ranges of improvement offered by standard medications utilized for the treatment of tremor. The authors concluded that peripheral nerve stimulation may provide a safe, well-tolerated, and effective treatment for transient relief of hand tremor symptoms, however future studies over time and multiple sessions are needed.

Isaacson et al (2020) evaluated the repeated home use of an FDA-cleared wrist-worn neuromodulation device in the Prospective Study for Symptomatic Relief of Essential Tremor with Cala Therapy (PROSPECT) trial. For each active treatment session, the device electrically stimulated the median and radial nerves for 40 minutes with an alternating burst pattern tuned to the frequency of each patient's tremor. The pre-specified co-primary endpoints were improvements on the clinician-rated Tremor Research Group Essential Tremor Rating Assessment Scale (TETRAS) and patient-rated Bain & Findley Activities of Daily Living (BF-ADL) dominant hand scores. Of the 263 enrolled patients, 205 completed the visit three follow-up and were included in the primary analysis. Results revealed a significant improvement in TETRAS and BF-ADL from pre- to post-stimulation at each clinic visit ($p<.0001$ for all comparisons). Pre-stimulation tremor levels were improved from Visit 1 to 3 on both TETRAS and BF-ADL ($p<.0001$ for both). Patients rated as "severe" or moderate" improved with both TETRAS (49.3% at baseline to 21% at study exit) and BF-ADL (64.8% at baseline to 23% at study exit) scoring. Tremor power is a calculation of amplitude and frequency. Tremor power decreases with lower amplitude motions and lower frequency motions. Tremor power was also noted to significantly improve with therapy from pre- to post-stimulation ($p<.0001$). No device-related serious adverse events were reported. Non-serious device related adverse events occurred in 18% of patients (e.g., persistent skin irritation, sore/lesion, discomfort, electrical burns, and minor skin irritation). Conclusions were that the repeated in-home use of this neuromodulation device over three months was effective and safe for patients with essential tremor. Limitations identified were the open-label, single-arm design, the lack of consensus for the definition of clinically meaningful improvement in TETRAS or BF-ADL, as well as the exclusion of 58 patients who exited the study early from the pre-specified primary and secondary endpoint analyses.

Next Annual Review:	March 2027

DISCLAIMER

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgement when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

PROCEDURE CODES

92521, 92522, 92523, 92524, 92507, 92508, 92526

DESCRIPTIONS

Speech therapy services are performed to meet the functional needs of an individual who suffers from a communication impairment and/or swallowing disorder due to illness, injury, or congenital anomaly. Speech therapy services are provided as a means of medical treatment as opposed to education, training, prevention, or conditioning. Speech therapy services require the judgement, knowledge, and skills of a qualified provider of speech therapy due to the complexity and sophistication of the therapy and the physical condition of the patient.

Speech therapy services may be habilitative or rehabilitative in nature.

- **Rehabilitation services** are health care services that help a person keep, get back, or improve skills and functioning for daily living that have been lost or impaired because a person was sick, hurt, or disabled.

- **Habilitation services** are health care services that help a person keep, learn, or improve skills and functioning for daily living. They include the management of limitations and disabilities, including services or programs that help maintain or prevent deterioration in physical, cognitive, or behavioral function.
    - Refer to specific member contracts for availability of benefits, if any, relating to habilitative services.

POSITION STATEMENT

CDPHP administers benefits for speech therapy services as outlined below.

Outpatient Speech Therapy

An initial speech and language evaluation is covered when ordered by a physician to determine the need for medically necessary treatment as described below.

CDPHP administers benefits for speech therapy treatment when all of the following criteria are met.

1. Speech therapy services are considered medically necessary only when such therapy is related to the treatment or diagnosis of a physical illness or injury (in the case of a covered child, this includes a medically diagnosed congenital defect.) The following are examples (not all-inclusive) of common medical disorders and resulting communication deficits that may necessitate active rehabilitative therapy:
    - Neurologic deficits as a result of a cerebral vascular accident or cerebral injury affecting swallowing, oral-motor strength and coordination, speech, or language.
    - Laryngeal cancer, laryngeal trauma, and trauma related dysphonia.
    - Oro-pharyngeal trauma or surgery affecting voice, such as laryngectomy or post-surgical vocal fold nodules.
    - Therapy for vocal cord nodules to reduce the trauma to the vocal cords caused by vocal cord apposition during phonation, and to prevent further nodule development.
    - Congenital (i.e., present at birth) anatomic defects that affect swallowing or speech where functional improvement is predicted through speech therapy (e.g., cleft palate and cleft lip).
    - Children with speech delay due to documented, acquired hearing loss (e.g., repeated ear infections resulting in hearing loss).
    - Rehabilitative therapy after cochlear implantation.
    - Acute hoarseness non-responsive to voice rest such as:
        - Sulcus vocalis
        - Dysphonia plica ventricularis
        - Early vocal fold nodule formation
        - Neurogenic, myopathic, and apraxic dysphonia
        - Spasmodic dysphonia (unresponsive to injection)

- Paradoxical vocal fold motion
- Vocal fold paralysis

2. Services are recommended by a physician.

3. Services are provided by a qualified provider of speech therapy services who is performing within the scope of license (e.g., speech therapist/pathologist, speech-language pathologist).

4. Treatment conforms to a written plan of care by a speech therapist specific to the enrollee's diagnosed impairment or condition to include the following: speech/language diagnosis with date of onset, treatment techniques and interventions to be used (amount, frequency, and duration required to achieve measurable goals), the nature, extent, and severity of the functional impairment, and an anticipated outcome.

5. Services are considered medically necessary only if there is a reasonable expectation that speech therapy will achieve measurable improvement in an enrollee's function in a reasonable and predictable period of time.

Autism Spectrum Disorder

In accordance with New York State's autism mandate, benefits are provided for covered therapeutic services, to include those for habilitative purposes, necessary to develop, maintain, or restore, to the greatest extent practicable, functioning of an individual when such services are provided by a licensed or certified speech therapist for the treatment of autism spectrum disorder. Such benefits will apply only to those plans to which the mandate applies.

POLICY CONSIDERATIONS

Benefits for speech therapy services (CPT code 92507, 92508) are subject to all applicable contract limitations and appropriate visit cost-share as stated in the enrollee's contract. Enrollee benefit period begins with the initial treatment.

The speech therapist must document objectively measurable function loss, must state objectively measurable speech therapy goals meeting and significant practical restorative need within a reasonable period of time.

Benefit coverage, for up to a maximum of six visits, will be provided for establishment of maintenance programs. However, no coverage will be provided for the continuation of maintenance programs (maintenance begins when the therapeutic goals of a treatment plan have been achieved and when no further functional progress is apparent or expected to occur).

Swallowing/feeding therapy is considered medically necessary for individuals with swallowing dysfunction (dysphagia) and children with a feeding disorder when all of the following criteria is met:

POLICY NAME: SPEECH LANGUAGE/PATHOLOGY SERVICES

- The swallowing or feeding disorder (92526) is the result of an underlying medical condition. Services performed by a speech language pathologist may include instruction and/or assistance in dietary modifications, compensatory swallowing techniques, proper head and body positioning, and facilitation exercises to improve oral-motor control.
- The medical necessity of the therapy has been demonstrated by the following:
    - an evaluation by a speech language pathologist which may document oral phase swallowing dysfunction without the need for additional testing and
    - results of testing with a videofluorographic swallowing study (VFSS) or other appropriate testing (i.e., esophageal manometry, endoscopy), as needed to document the pathology

- Meaningful improvement is expected from the therapy.

When a service or procedure that may be either habilitative or rehabilitative in nature is provided for **habilitative** purposes, the use of modifier 96 is required to indicate that the service or procedure provided was a habilitative service.

Services or procedures provided for rehabilitative purposes do not require the use of a modifier.

All speech therapy services are subject to retrospective review for medical appropriateness as defined by this policy.

Coverage will no longer be provided once the allowable maximum benefit is exhausted, even if the medical necessity criteria stated above is met.

EXCLUSIONS

Speech therapy is not considered medically necessary for dysfunctions that are self-correcting, such as language therapy for young children with natural dysfluency or developmental articulation errors that are self-correcting.

Non-skilled services. Treatments are not considered medically necessary if they do not require the skills of a qualified provider of speech therapy services and are treatments that maintain function by using routine, repetitions, and reinforced procedures that are neither diagnostic nor therapeutic or procedures that may be carried out effectively by the patient, family, or caregivers.

Maintenance programs such as drills, techniques, and exercises that preserve the enrollee's present level of function and prevent regression of that function. Maintenance begins when the therapeutic goals of a treatment plan have been achieved and when no further functional progress is apparent or expected to occur.

Speech, voice therapy, or swallowing/feeding therapy that duplicates services already being provided as part of another therapy program through another therapy discipline (i.e.,

occupational therapy). When multiple therapies are used, each must have separate written treatment plans and must provide significantly different treatments.

Speech therapy that duplicates services being provided by a federal or state governmental agency (i.e., Early Intervention Program), by a school district (Individualized Educational Program) or by a developmental learning center that are sufficient in meeting the needs of an individual.

Sensory (Auditory) Integration Therapy.

Voice therapy for muscle tension dysphonia (functional dysphonia).

Swallowing/feeding therapy for food aversion without an underlying medical condition.

Speech therapy for ankyloglossia (tongue-tie).

CDPHP PRODUCT VARIATIONS

CHILD HEALTH PLUS	Subject to all terms and conditions noted above in the policy.
MEDICARE ADVANTAGE	Subject to all terms and conditions noted above in the policy. • Benefits to include unlimited days of medically necessary speech therapy, including treatment for individuals with mental retardation when co-morbid disorders such as aphasia or dysarthria are present. Includes therapy that would otherwise be covered as an inpatient and is provided under the care of a physician pursuant to a written plan of treatment.
SELECT PLAN/HARP	Subject to all terms and conditions noted above in the policy. Benefit coverage includes unlimited medically necessary speech therapy visits.
SMALL GROUP/ COMMERCIAL INDIVIDUAL	Rehabilitative speech therapy services are covered only when: • Therapy is related to the treatment or diagnosis of a physical illness or injury (in the case of a covered child, this includes a medically diagnosed congenital defect); **and** • Therapy is ordered by a physician; **and** • The enrollee has been hospitalized or has undergone surgery for such illness or injury.

POLICY NAME: SPEECH LANGUAGE/PATHOLOGY SERVICES

	Covered speech therapy services must begin within six months of the later to occur: • The date of the injury or illness that caused the need for the therapy; • The date of discharged from the hospital where the surgical treatment was rendered; **or** • The date outpatient surgical care is rendered. Habilitation services consisting of speech therapy are covered in the outpatient department of a facility or in a health care professional's office.

POLICY HISTORY

This section is intended to provide only highlights of the policy changes. The policy should always be reviewed in its entirety to ensure a comprehensive understanding of coverage.

Effective Date	Update
5/1/2025 *No change to effective date of policy	Updated information for documentation of swallowing/feeding therapy.
5/1/2025	Under exclusions section, added treatment for ankyloglossia.
6/1/2023 *No change to effective date of policy	Under swallowing therapy added examples of testing that could be performed to confirm dysphagia diagnosis.
6/1/2023	Removed specific diagnoses from the exclusion section.
1/1/21 *No change to effective date of policy	Updates did not require criteria change. Removed visit limitations under product variations as contracts are the best source for identifying limits.

MEDICAL POLICY

Medical Policy Title	**Spine Procedures for Managed Medicaid (MMC), Health and Recovery Plan (HARP), Child Health Plus (CHP), and Essential Plan (EP) Members**
Policy Number	**7.01.126**
Current Effective Date	**January 01, 2027**
Next Review Date	**September 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service.

Cervical Spine Procedures:

- Arthrodesis
- Corpectomy
- Disc Arthroplasty (Replacement)
- Anterior Cervical Decompression with Fusion (ACDF) or without Fusion; **or** Posterior Cervical Decompression with or without Fusion
- Combined Anterior AND Posterior Cervical Decompression with or without Fusion

Lumbar-Sacral Spine Procedures:

- Arthrodesis
- Decompression
- Lumbar Fusion: Single Level, with or without Decompression
- Lumbar Fusion: Repeat, with or without Decompression
- Lumbar Spine Discectomy/Microdiscectomy
- Lumbar Osteotomy
- Percutaneous Lumbar Discectomy / Disc Decompression
- Pediatric Scoliosis

POLICY STATEMENT(S)

Cervical Spine Procedures

Cervical Arthrodesis

I. Cervical arthrodesis is considered **medically appropriate** when **ALL** the following are met:

A. The individual has **any** of the following cervical spine conditions:
    1. Herniated disc;
    2. Segmental instability;
    3. Spondylosis; **or**
    4. Spinal canal stenosis;

B. Clinical presentation includes **any** of the following:
    1. Myelopathy (e.g., bowel or bladder dysfunction, gait disturbance, hyperreflexia, upper extremity weakness);
    2. Measurable neurologic impairment (e.g., motor weakness, sensory loss, abnormal reflexes); **or**
    3. Radiculopathy (e.g., numbness, paresthesias, or radiating upper extremity pain);

C. Conservative management meets **either** of the following:
    1. No conservative management is required for **any** of the following:
        a. Cervical myelopathy;
        b. Progressive neurologic deterioration;
        c. Severe spinal cord compression with significant neurologic findings;
        d. Segmental instability requiring surgical stabilization;
        e. Tumor, infection or instability resulting from trauma; **or**
    2. For all other indications, conservative management must include **both** the following:
        a. Physical therapy (PT) meets **all** the following:
            i. Participation for a minimum of 6 weeks during the previous 6 months;
            ii. Symptoms or functional impairments failed to improve;
            iii. Supervised by a licensed PT, chiropractor, or through tele-rehab PT; **and**
        b. Pain management includes **all** the following:
            i. Interventional pain management strategies (e.g., epidural steroid injections, facet injections, or selective nerve root blocks) have been considered, when clinically indicated;
            ii. Non-steroidal anti-inflammatory drugs (NSAIDs) for a minimum of 4 weeks, unless contraindicated; **and**
            iii. Non-pharmacologic pain management such as activity modification, rest periods, splinting, or therapeutic exercises;

D. Preoperative cervical spine imaging obtained within 6 months prior to surgery includes **any**

of the following:

1. Computed tomography (CT);
2. CT Myelogram;
3. Magnetic resonance imaging (MRI); **or**
4. Radiographs (x-rays) as supplemental (e.g., flexion/extension).

II. Cervical arthrodesis is considered **not medically necessary** for **ANY** of the following contraindications:

A. Uncontrolled diabetes with hemoglobin A1C (HbA1C) greater than 8%;

B. Medical comorbidity with increased surgical risk (e.g., anemia, malnutrition, severe cardiovascular or pulmonary disease);

C. Active infection, systemic or localized to the operative field;

D. Allergy or hypersensitivity to implant materials; **or**

E. Compromised bone integrity due to severe osteoporosis or metabolic bone disease that has not been adequately treated.

<u>Cervical Spine Corpectomy</u>

III. Anterior cervical spine corpectomy is considered **medically necessary** when **ALL** the following are met:

A. Cervical fusion is performed as part of the procedure due to instability, given fusion criteria are met;

B. A complete or partial cervical corpectomy is planned with removal of at least one-half of a vertebral body;

C. Treatment is for **one (1) or more** of the following:

1. Infection;
2. Tumor (benign or malignant);
3. Compression located at or posterior to the vertebral body level; **or**
4. Trauma.

<u>Cervical Disc Arthroplasty (CDA)</u>

IV. Cervical disc arthroplasty (artificial disc replacement) is considered **medically appropriate** when **ALL** the following are met:

A. Symptomatic cervical disc disease, evidenced by **both** of the following:

1. Documented findings correlate with neural compression at the cord or nerve root level (e.g., altered reflexes, dermatomal sensory loss, motor weakness); **and**

2. Radiculopathy and/or myelopathy attributable to degenerative disc disease at one (1) or two (2) levels between C3 and C7, with central, lateral recess, or foraminal compression (e.g., disc herniation, spondylotic osteophyte);

B. Conservative non-surgical management meets **either** of the following:

1. No conservative management is required when **any** of the following is documented:
    a. Objective neurological deterioration (e.g., increasing motor loss) across serial examinations;
    b. Myelopathy attributable to spinal cord compression (e.g., cord signal change on MRI);
    c. New-onset bowel or bladder dysfunction due to cervical spinal cord compression;
    d. Symptoms of nerve root or spinal cord compression are severe or rapidly progressive, requiring hospitalization or immediate surgery;
    e. Motor weakness is significant or rapidly progressing (e.g., motor grade ≤3/5, or interference with activities of daily living); **or**
2. For all other indications, conservative management must include **both** of the following:
    a. Physical therapy (PT) meets **all** the following:
        i. Supervised by a licensed PT, chiropractor, or through tele-rehab PT;
        ii. Participation for a minimum of 6 weeks during the previous 6 months; **and**
        iii. Symptoms or functional impairments failed to improve;
    b. Pain management includes **all** the following:
        i. Interventional pain management strategies (e.g., epidural steroid injections, facet injections, or selective nerve root blocks) have been considered, when clinically indicated;
        ii. Non-steroidal anti-inflammatory drugs (NSAIDs) for a minimum of 4 weeks, unless contraindicated; **and**
        iii. Non-pharmacologic pain management such as activity modification, rest periods, splinting, or therapeutic exercises;

C. Advanced imaging (MRI or CT) demonstrate neural compression at the cord or nerve root level(s) concordant with the clinical presentation;

D. Documentation confirms skeletal maturity;

E. The cervical disc replacement device is used in accordance with U.S. Food and Drug Administration (FDA)-approved labeling.

V. Cervical disc arthroplasty (artificial disc replacement) is considered **not medically necessary** for **ANY** of the following contraindications:

A. Uncontrolled diabetes with hemoglobin A1C (HbA1C) greater than 8%;

B. Medical comorbidity with increased surgical risk (e.g., anemia, malnutrition, severe cardiovascular or pulmonary disease);

C. Active malignancy involving the cervical spine or metastatic disease;

D. Allergy or sensitivity to materials used in the implant (e.g., titanium, polyethylene, cobalt, chromium, molybdenum);

E. Immune-mediated or inflammatory arthropathy, including the spondyloarthritis, (e.g., ankylosing spondylitis, psoriatic arthritis);

F. Metabolic bone disease (e.g., Paget disease, osteomalacia);

G. Marked cervical instability (e.g., greater than 3.5 millimeters translation and/or angular difference greater than 11 degrees);

H. Clinically significant cervical anatomical deformity (e.g., fixed kyphosis);

I. Facet arthropathy graded as moderate or worse at the involved level;

J. Active infection, local or systemic;

K. Ossification of the posterior longitudinal ligament (OPLL) at the level to be treated;

L. Osteoporosis or osteopenia;

M. Severe spondylosis (e.g., bridging osteophytes, greater than 50% loss of disc height, or segmental motion less than 2 degrees) and past surgical history at the requested level; **or**

N. Structural vertebral body deficiency or deformity resulting from prior trauma (e.g., malunion, nonunion, or fracture callus).

<u>Anterior Cervical Decompression with Fusion (ACDF) or without Fusion; or Posterior Cervical Decompression with or Without Fusion</u>

VI. Anterior cervical decompression with fusion (ACDF) or without fusion; or posterior cervical decompression with or without fusion (laminectomy, laminoforaminotomy, laminoplasty) is considered **medically appropriate** when **ALL** the following are met:

A. For fusion procedures only: evidence supports that the individual is nicotine-free by **either** of the following:

1. Individual is a never smoker; **or**

2. Cotinine testing (serum, urine, or saliva) results less than or equal to 10 ng/mL, confirming the individual has refrained from nicotine use (e.g., smoking, use of smokeless tobacco products, or nicotine replacement therapy) for a minimum of six (6) weeks prior to the planned surgery;

Exception: Urgent or emergent cervical fusion is not subject to nicotine abstinence requirements when surgical delay may compromise the individual's clinical status.

B. When documentation meets **one (1)** of the following:
   1. Cervical myelopathy or radiculopathy attributed to cervical deformity, herniated disc, segmental instability, or spondylosis when **both** of the following are documented:
      a. Conservative management meets **both** of the following:
         i. Physical therapy (PT) meets **all** the following:
            a) Participation for a minimum of 6 weeks during the previous 6 months;
            b) Symptoms or functional impairments failed to improve; **and**
            c) Supervised by a licensed PT, chiropractor, or through tele-rehab PT;
         ii. Pain management includes **all** the following:
            a) Interventional pain management strategies (e.g., epidural steroid injections, facet injections, or selective nerve root blocks) have been considered, when clinically indicated;
            b) Non-steroidal anti-inflammatory drugs (NSAIDs) for a minimum of 4 weeks, unless contraindicated; **and**
            c) Non-pharmacologic pain management such as activity modification, rest periods, splinting, or therapeutic exercises;
      b. CT or MRI obtained within 6 months prior to surgery identifies neural compression at the cord or nerve root(s) levels concordant with the clinical presentation;

   OR

   2. Decompression, with or without fusion, may be performed as an initial surgical intervention without a trial of conservative management when **all** the following are documented:
      a. Symptoms of cervical myelopathy associated with spinal cord compression;
      b. Neurological impairments are progressing/worsening; **and**
      c. Objective clinical findings include **any** of the following:
         i. Clonus;
         ii. Hyperreflexia (exaggerated deep tendon reflexes);
         iii. Impaired walking or loss of coordination;
         iv. Motor weakness; **or**
         v. Positive Babinski or Hoffmann sign;

   OR

   3. Decompression with fusion may be performed as an initial surgical intervention without

a trial of conservative management when **all** the following are documented:

a. Significant neural compression (spinal cord or nerve root) from infection, trauma, or tumor, which may be demonstrated by spinal canal narrowing and/or clinical findings (e.g., loss of hand dexterity or gait/balance impairment); **and**

b. X-rays identify fracture or segmental instability, defined by **either** of the following:

i. C1-level subluxation with an atlantodental interval greater than 3 mm in an adult or 5 mm in a child; **or**

ii. Sagittal plane measurement, demonstrating **either** of the following:

a) Angulation greater than 11 degrees at a single motion segment; **or**

b) Anterior translation greater than 3.5 mm accompanied by spinal cord dysfunction or radiculopathy;

OR

4. Decompression without fusion may be performed as an initial surgical intervention without a trial of conservative management when **all** the following are documented:

a. Imaging (X-ray) confirms no segmental instability; **and**

b. Significant neural compression (spinal cord or nerve root) from infection, trauma, or tumor, which may be demonstrated by spinal canal narrowing and/or clinical findings (e.g., loss of hand dexterity or gait/balance impairment).

VII. Cervical decompression or fusion is considered **not medically necessary** for **EITHER** of the following:

A. Decompression performed without fusion, when the spinal deformity requires stabilization (fusion);

B. The presence of **any** of the following contraindications:

1. Uncontrolled diabetes with hemoglobin A1C (HbA1C) is greater than 8%;

2. Medical comorbidity with increased surgical risk (e.g., anemia, malnutrition, severe cardiovascular or pulmonary disease);

3. Clinically insignificant or minimally symptomatic disease that does not produce a meaningful functional limitation (e.g., incidental imaging findings);

4. Neck pain in the absence of neurologic impairment, with no radiographic evidence of spinal cord or nerve root compression; **or**

5. Imaging findings are not consistent with the individual's reported symptoms or objective clinical examination findings.

<u>Combined Anterior AND Posterior Cervical Decompression, with or without Fusion</u>

VIII. Anterior and posterior cervical spine decompression, with or without fusion, is considered

medically appropriate when **ALL** the following are met:

A. Comorbid conditions are optimally managed;

B. Conservative management meets **both** of the following:

1. Physical therapy (PT) meets **all** the following:

a. Participation for a minimum of 6 weeks during the previous 6 months;

b. Symptoms or functional impairments failed to improve; **and**

c. Supervised by a licensed PT, chiropractor, or through tele-rehab PT;

2. Pain management includes **all** the following:

a. Interventional pain management strategies (e.g., epidural steroid injections, facet injections, or selective nerve root blocks) have been considered, when clinically indicated;

b. Non-steroidal anti-inflammatory drugs (NSAIDs) for a minimum of 4 weeks, unless contraindicated; **and**

c. Non-pharmacologic pain management such as activity modification, rest periods, splinting, or therapeutic exercises;

C. Imaging (CT, MRI, X-ray) reveals segmental instability or disc pathology;

D. Axial and non-radicular neck pain;

E. Anatomic source of pain (e.g., cervical facet [zygapophyseal] joint) has been identified and treated;

F. No more than two (2) levels are affected;

G. For fusion procedures only: evidence supporting that the individual is nicotine-free by **either** of the following:

1. Individual is a never smoker; **or**

2. Cotinine testing (serum, urine, or saliva) results less than or equal to 10 ng/mL, confirming the individual has refrained from nicotine use (e.g., smoking, use of smokeless tobacco products, or nicotine replacement therapy) for a minimum of six (6) weeks prior to the planned surgery;

Exception: Urgent or emergent cervical fusion is not subject to nicotine abstinence requirements when surgical delay may compromise the individual's clinical status.

IX. Cervical spine decompression or fusion is considered **not medically necessary** for the following:

A. Stand-alone decompression (without fusion) for spinal deformity (e.g. cervical kyphosis) requiring stabilization (fusion);

B. For **any** of the following contraindications:
   1. Uncontrolled diabetes with hemoglobin A1C (HbA1C) is greater than 8%;
   2. Medical comorbidity with increased surgical risk (e.g., anemia, malnutrition, severe cardiovascular or pulmonary disease);
   3. Clinically insignificant or minimally symptomatic disease that does not produce a meaningful functional limitation (e.g., incidental imaging findings);
   4. Neck pain in the absence of neurologic impairment, with no radiographic evidence of spinal cord or nerve root compression; **or**
   5. Imaging findings are not consistent with the individual's reported symptoms or objective clinical examination findings.

Lumbar-Sacral Spine Procedures

Lumbar Arthrodesis

X. Lumbar arthrodesis is considered **medically appropriate** when **ALL** the following are met:
   A. The individual has evidence of **any** of the following:
      1. Symptomatic degenerative spondylolisthesis;
      2. Neurogenic claudication or radiculopathy attributable to degenerative disease;
      3. Recurrent lumbar disc herniation necessitating segmental stabilization;
      4. Persistent, clinically significant axial low back pain accompanied by **either** of the following:
         a. Degenerative spondylolisthesis; **or**
         b. Neurogenic claudication
      5. Segmental instability demonstrated on imaging (e.g., abnormal motion on flexion-extension views); **or**
      6. Spinal deformity with associated symptoms (e.g., scoliosis);
   B. Symptom burden includes **either** of the following:
      1. Clinically significant pain; **or**
      2. Functional impairment that interferes with activities of daily living;
   C. Conservative management meets **either** of the following:
      1. No requirement for conservative management for **any** of the following indications:
         a. Cauda equina syndrome;
         b. Deteriorating or marked motor/sensory deficit (e.g., weakness, foot drop);
         c. Instability or neurologic impairment secondary to spinal infection or tumor for which

surgical intervention is indicated; **or**

d. Traumatic spinal instability;

OR

2. For all other indications, conservative management includes **both** of the following:
   a. Physical therapy (PT) meets **all** the following:
      i. Participation for a minimum of 6 weeks during the previous 6 months;
      ii. Symptoms or functional impairments failed to improve; **and**
      iii. Supervised by a licensed PT, chiropractor, or through tele-rehab PT;
   b. Pain management includes **all** the following:
      i. Interventional pain management strategies (e.g., epidural steroid injections, facet injections, or selective nerve root blocks) have been considered, when clinically indicated;
      ii. Non-steroidal anti-inflammatory drugs (NSAIDs) for a minimum of 4 weeks, unless contraindicated; **and**
      iii. Non-pharmacologic pain management such as activity modification, rest periods, splinting, or therapeutic exercises;

D. Preoperative lumbar spine imaging includes **both** of the following:
   1. Findings consistent with clinical presentation; **and**
   2. Obtained within 6 months prior to surgery using **any** of the following:
      a. CT;
      b. CT myelogram;
      c. MRI; **or**
      d. X-ray.

XI. Lumbar arthrodesis is considered **not medically necessary** for **ANY** of the following contraindications:
   A. Uncontrolled diabetes with hemoglobin A1C (HbA1C) is greater than 8%;
   B. Medical comorbidity with increased surgical risk (e.g., anemia, malnutrition, severe cardiovascular or pulmonary disease);
   C. Clinically insignificant or minimally symptomatic disease that does not produce a meaningful functional limitation (e.g., incidental imaging findings);
   D. Active infection, systemic or localized to the operative field, except when the fusion is intended to treat the infection; **or**

E. Compromised bone integrity due to severe osteoporosis or metabolic bone disease that has not been adequately treated.

Lumbar Spine Decompression

XII. Lumbar decompression (facetectomy, foraminotomy, laminectomy, laminotomy) is considered **medically appropriate** when **ALL** the following are met:

A. Subjective symptoms include **either** of the following:

1. Significant level of pain on a daily basis; **or**
2. Significant functional impairment impacting activities of daily living (e.g., household tasks, prolonged standing, walking);

B. Preoperative lumbar spine imaging (e.g., CT, MRI) includes **both** of the following:

1. Obtained within 6 months prior to surgery; **and**
2. Stenosis (central canal, lateral recess, or foraminal) at the identified level(s) is consistent with clinical presentation and findings;

C. Documentation confirms **either** of the following clinical presentations:

1. Neurogenic claudication includes **all** the following:
    a. Symptoms involve the low back, buttocks, or legs, with **at least one (1)** of the following documented:
        i. cramping;
        ii. decreased strength,
        iii. heaviness;
        iv. numbness
        v. pain; **or**
        vi. paresthesia;
    b. Functional impairment related to limitations in ambulation or standing;
    c. Symptom relief from sitting or lumbar flexion; **and**
    d. Symptom exacerbation with standing or walking;

OR

2. Radiculopathy secondary to lumbar stenosis includes **all** the following symptoms:
    a. Pain radiating into the buttock or legs is ongoing;
    b. A symptom pattern that follows the distribution of the involved nerve root; **and**
    c. Documentation of **one (1) or more** of the following:

i. Sensory loss in a dermatomal pattern;
ii. Nerve root–specific muscle weakness;
iii. Reproduction of symptoms with the contralateral (crossed) straight leg raise;
iv. Positive femoral nerve stretch maneuver;
v. Positive straight leg raise (SLR) or comparable nerve tension sign; **or**
vi. Reflex abnormality (e.g., absent or diminished);

D. Conservative management meets **either** of the following:
1. No requirement for conservative management for **any** of the following indications:
a. Cauda equina syndrome;
b. Neurologic deterioration over time (e.g., declining functional capacity, new/worsening foot drop or motor strength);
c. Motor deterioration progressed over a short period of time;
d. Significant motor weakness of 3/5 or less on manual muscle testing; **or**
e. Significant neurologic compromise resulting from lumbar neural compression, supported by imaging findings consistent with the clinical presentation;

OR

2. For all other indications, conservative management includes **both** of the following:
a. Physical therapy (PT) meets **all** the following:
i. Participation for a minimum of 6 weeks during the previous 6 months;
ii. Symptoms or functional impairments failed to improve; **and**
iii. Supervised by a licensed PT, chiropractor, or through tele-rehab PT;
b. Pain management includes **all** the following:
i. Interventional pain management strategies (e.g., epidural steroid injections, facet injections, or selective nerve root blocks) have been considered, when clinically indicated;
ii. Non-steroidal anti-inflammatory drugs (NSAIDs) for a minimum of 4 weeks, unless contraindicated; **and**
iii. Non-pharmacologic pain management such as activity modification, rest periods, splinting, or therapeutic exercises.

XIII. Lumbar decompression (facetectomy, foraminotomy, laminectomy, laminotomy) is considered **not medically necessary** for **EITHER** of the following contraindications:

A. Uncontrolled diabetes with hemoglobin A1C (HbA1C) is greater than 8%;

B. Medical comorbidity with increased surgical risk (e.g., anemia, malnutrition, severe cardiovascular or pulmonary disease).

Lumbar Fusion: Single Level, with or without Decompression

XIV. Single level lumbar fusion, with or without decompression (laminectomy, laminotomy, facetectomy, foraminotomy) is considered **medically appropriate** when **EITHER** of the following are met:

A. For chronic axial low back pain attributed to degenerative disc disease and a condition requiring spinal stabilization when **all** the following are met:

1. Axial low back pain without primary symptoms of radiculopathy has persisted for a minimum of 6 months;
2. Conservative management includes **both** the following:
    a. Physical therapy (PT) meets **all** the following:
        i. Participation for a minimum of 6 weeks during the previous 6 months;
        ii. Symptoms or functional abilities failed to improve; **and**
        iii. Supervised by a licensed PT, chiropractor, or through tele-rehab PT; **and**
    b. Pain management includes **all** the following:
        i. Interventional pain management trial (e.g., epidural steroid injections, facet injections, or selective nerve root blocks), unless documentation supports rationale for why trial is not appropriate;
        ii. Non-steroidal anti-inflammatory drugs (NSAIDs) for a minimum of 4 weeks, unless contraindicated; **and**
        iii. Non-pharmacologic pain management such as activity modification, rest periods, splinting, or therapeutic exercises;
3. Preoperative imaging (e.g., CT, MRI, X-rays) obtained within 6 months prior to the procedure confirms a structural abnormality at the requested fusion level that concordant with reported symptoms, objective examination findings, and overall clinical picture;
4. Documented objective findings confirming a structural abnormality for which fusion is needed to restore segmental stability, evidenced by **any** of the following:
    a. Spondylolisthesis accompanied by instability on dynamic or side-by-side comparative imaging;
    b. Abnormal segmental motion, defined as more than 3 mm of translational displacement between flexion and extension views on dynamic X-rays; **or**
    c. Symptomatic, localized spinal deformity that requires operative stabilization;

5. Evidence supporting that the individual is nicotine-free by **either** of the following:
    a. Individual is a never smoker; **or**
    b. Cotinine testing (serum, urine, or saliva) results less than or equal to 10 ng/mL, confirming the individual has refrained from nicotine use (e.g., smoking, use of smokeless tobacco products, or nicotine replacement therapy) for a minimum of six (6) weeks prior to the planned surgery.

    Exception: Urgent or emergent lumbar fusion is not subject to nicotine abstinence requirements when surgical delay may compromise the individual's clinical status.

OR

B. For lumbar fusion as first line treatment, without a trial of non-surgical conservative management, when **both** of the following are met:
    1. **All** the following are met:
        a. Documentation of **any** of the following conditions:
            i. Cauda equina syndrome with bowel or bladder dysfunction accompanied by neurologic deficits;
            ii. Acute, progressive and significant neurological impairment (e.g., motor weakness, reflex changes); **or**
            iii. Spinal infection, tumor or malignancy;
        b. Preoperative imaging obtained within 6 months prior to the procedure confirms a structural abnormality at the requested fusion level concordant with reported symptoms and objective examination findings; **and**
        c. Evidence confirms that fusion is necessary to restore segmental stability; **and**
    2. Evidence supporting that the individual is nicotine-free by **either** of the following:
        a. Individual is a never smoker; **or**
        b. Cotinine testing (serum, urine, or saliva) results less than or equal to 10 ng/mL, confirming the individual has refrained from nicotine use (e.g., smoking, use of smokeless tobacco products, or nicotine replacement therapy) for a minimum of six (6) weeks prior to the planned surgery.

    Exception: Urgent or emergent lumbar fusion is not subject to nicotine abstinence requirements when surgical delay may compromise the individual's clinical status.

<u>Repeat Lumbar Fusion at the Same Level</u>

XV. Repeat lumbar fusion (arthrodesis) (with or without decompression) at the same level in adult patients is considered **medically necessary** for **EITHER** of the following indications:
    A. For malposition or failure of implant/instrumentation or structural bone graft, when the

following criteria are met:

1. Post-operative imaging shows evidence of malposition or failure of the implant/instrumentation or structural bone graft (e.g., migration, pedicle screw breakage, pedicle screw loosening, dislodged hooks, rod breakage, rod bending, rod loosening, loss of curve correction, decompensation, etc.);

OR

B. For symptomatic Pseudoarthrosis when **all** the following criteria are met:
   1. Greater than 6 months since the prior lumbar fusion;
   2. Subjective symptoms include significant level of pain on a daily basis defined as clinically significant functional impairment (e.g., inability to perform household chores, prolonged standing, etc.);
   3. Post-operative physical exam findings are concordant with the individual's symptoms;
   4. Less than clinically meaningful improvement with 6 weeks of non-surgical treatment with **both** of the following (unless contraindicated):
      a. Prescription strength analgesics, steroids, gabapentinoids or NSAIDs; **and**
      b. Provider-directed exercise program prescribed by a physical therapist, chiropractic provider, osteopathic or allopathic physician;
   5. Post-operative imaging (performed at no less than six (6) months after the lumbar fusion) shows pseudoarthrosis at the requested level(s);
   6. Post-operative MRI/CT findings are concordant with the individual's symptoms;
   7. Evidence supporting that the individual is nicotine-free by **either** of the following:
      a. Individual is a never smoker; **or**
      b. Cotinine testing (serum, urine, or saliva) results less than or equal to 10 ng/mL, confirming the individual has refrained from nicotine use (e.g., smoking, use of smokeless tobacco products, or nicotine replacement therapy) for a minimum of six (6) weeks prior to the planned surgery.

      Exception: Urgent or emergent lumbar fusion is not subject to nicotine abstinence requirements when surgical delay may compromise the individual's clinical status.

<u>Lumbar Spine Discectomy/Microdiscectomy</u>

XVI. A lumbar discectomy/microdiscectomy is considered **medically appropriate** when **either** of the following is met:

A. For urgent conditions, microdiscectomy is indicated as first-line treatment without a trial of conservative management when **either** of the following is documented:
   1. Cauda equina syndrome (e.g., saddle anesthesia, bowel or bladder dysfunction); **or**

2. Motor impairment is severe (e.g., weakness ≤3/5) or worsening over a short period of time (e.g., across several examinations);

OR

B. For intervertebral disc herniation, when **all** the following are met:
   1. MRI confirms a disc herniation that is concordant with the clinical presentation;
   2. Functional impairment is attributable to radiculopathy;
   3. Conservative management meets **both** of the following:
      a. Physical therapy (PT) meets **all** the following:
         i. Participation for a minimum of 6 weeks during the previous 6 months;
         ii. Symptoms or functional limitations failed to improve; **and**
         iii. Supervised by a licensed PT, chiropractor, or through tele-rehab PT; **and**
      b. Pain management includes **all** the following:
         i. Interventional pain management strategies (e.g., epidural steroid injections, facet injections, or selective nerve root blocks) have been considered, when clinically indicated;
         ii. Non-steroidal anti-inflammatory drugs (NSAIDs) for a minimum of 4 weeks, unless contraindicated; **and**
         iii. Non-pharmacologic pain management such as activity modification, rest periods, splinting, or therapeutic exercises.

XVII. A lumbar discectomy/microdiscectomy is considered **not medically necessary** for **ANY** of the following contraindications:
   A. Uncontrolled diabetes with hemoglobin A1C (HbA1C) is greater than 8%;
   B. Medical comorbidity with increased surgical risk (e.g., anemia, malnutrition, severe cardiovascular or pulmonary disease);

<u>Lumbar Osteotomy</u>

XVIII. Lumbar spinal osteotomy is considered **medically appropriate** when **ALL** the following are met:
   A. Spinal alignment abnormality includes **both** of the following:
      1. Documented for a minimum of 6 months; **and**
      2. Standing X-rays confirm the presence **of any** of the following:
         a. Flatback deformity;
         b. Fixed kyphotic deformity;

c. Fixed sagittal-plane deformity;
d. Moderate-to-severe sagittal malalignment;
e. Sagittal malalignment following prior fusion that causes functional impairment; **or**
f. Symptomatic spinal deformity for which surgical correction is indicated;

B. Associated symptoms include **any** of the following:
1. Neurologic impairment confirmed by objective findings on physical examination;
2. Radicular symptoms that correspond with findings on diagnostic imaging;
3. Neurogenic claudication;
4. Chronic midline (axial) low back pain caused by the deformity;
5. Difficulty walking, including decreased tolerance;
6. Impaired ability to remain upright;
7. Impaired ability to maintain a horizontal gaze due to deformity; **or**
8. Meaningful loss of function affecting the performance of activities of daily living;

C. Preoperative imaging includes **all** the following:
1. Obtained within 3 to 6 months prior to surgery;
2. Advanced imaging of the lumbar spine (CT or MRI);
3. Standing X-rays document the presence of a spinal alignment abnormality; and
4. Correlation between imaging findings, clinical findings, and the planned corrective procedure;

D. Conservative management meets **either** of the following:
1. No conservative management is required for **any** of the following:
a. Cauda equina syndrome;
b. Bowel or bladder dysfunction caused by compression of neural structures;
c. Neurologic deficit continues to worsen over time; **or**
d. Neurologic decline occurring over a short interval;
2. For all other indications, conservative pain management includes **all** the following:
a. Pharmacological treatment with **either** of the following, as clinically indicated:
i. Analgesics or anti-inflammatory medication (e.g., NSAIDs); **or**
ii. Corticosteroid injection(s);
b. Participation in **at least one (1)** of the following treatments:

i. Activity modification and/or avoidance of aggravating activities;
ii. Acupuncture;
iii. Biofeedback techniques;
iv. Cognitive behavioral therapy (CBT);
v. Transcutaneous electrical nerve stimulation (TENS);

c. Physical therapy (PT) meets **all** the following:
i. Participation for a minimum of 6 weeks during the previous 6 months;
ii. Symptoms or functional limitations failed to improve; **and**
iii. Supervised by a licensed PT, chiropractor, or through tele-rehab PT.

XIX. Lumbar spinal osteotomy is considered **not medically necessary** for **ANY** of the following contraindications:

A. Uncontrolled diabetes with hemoglobin A1C (HbA1C) is greater than 8%;
B. Medical comorbidity with increased surgical risk (e.g., anemia, malnutrition, severe cardiovascular or pulmonary disease);
C. Bleeding disorder that cannot be adequately corrected;
D. Compromised bone integrity, including severe osteoporosis.
E. Hypersensitivity to bone cement or osseointegration/augmentation materials; **or**
F. Unresolved infection, including infection in the bloodstream;

<u>Percutaneous Lumbar Disc Decompression / Discectomy</u>

XX. Percutaneous lumbar disc decompression or discectomy procedures are considered **investigational**, include but are not limited to:

A. Automated percutaneous lumbar discectomy (APLD) (e.g., Nucleotome);
B. Mechanical percutaneous discectomy (e.g., Dekompressor);
C. Percutaneous laser disc decompression (PLDD);
D. Nucleoplasty (also known as plasma disc decompression [PDD], radiofrequency coblation disc decompression, or plasma-mediated ablation; e.g., SpineWand);
E. Targeted disc decompression (TDD).

<u>Pediatric Scoliosis</u>

XXI. Surgical management of scoliosis in the pediatric population is considered **medically appropriate** when **ALL** of the following are met:

A. The clinical presentation meets **all** the following:

1. Physical examination findings include **any** of the following:
    a. Unequal shoulder or pelvic (iliac crest) heights;
    b. Trunk shift or lateral lean in posture;
    c. Paraspinal/rib prominence elicited on the Adams forward-bend maneuver;
    d. Asymmetric waist contour or hip alignment; **or**
    e. Clinically apparent curvature of the spine;
2. Diagnostic imaging obtained within the preceding 12 months confirms **any** of the following:
    a. Cobb measurement of 50 degrees or more in a child at or approaching the end of skeletal growth (maturity);
    b. Early-onset scoliosis exhibiting a curve exceeding 40 degrees with substantial remaining growth potential;
    c. Documented curve advancement to a Cobb measurement of 45 degrees or more despite a trial of non-operative conservative management;
    d. Worsening deformity producing truncal imbalance, loss of function, or a demonstrable likelihood of continued progression;
3. Preoperative imaging includes **all** the following:
    a. Obtained within the last 12 months of the planned procedure;
    b. Documentation of the measured Cobb angle;
    c. Imaging findings are concordant with the diagnosed deformity and planned surgical correction;
    d. X-rays including standing PA and lateral spine; **and**
    e. MRI has been obtained when **any** of the following are identified:
        i. Abnormal findings on neurologic examination;
        ii. Atypical curve features; **or**
        iii. Rapid curve progression;

B. Treatment includes **both** of the following:
1. Non-surgical conservative management includes **both** of the following:
    a. Ongoing use of brace or spinal orthosis until **either** of the following:
        i. The individual reaches skeletal maturity prior to surgical consideration; **or**
        ii. Until the curve advances beyond 45 degrees; **and**
    b. Physical therapy (PT) meets **all** the following:

i. Participation for a minimum of 6 weeks during the previous 6 months;

ii. Symptoms or functional impairments failed to improve; **and**

iii. Supervised by a licensed PT, chiropractor, or through tele-rehab PT; **and**

2. Surgical management includes **any** of the following:
   a. Posterior instrumented spinal fusion indicated for curves in the range of approximately 45 to 50 degrees or greater;
   b. Vertebral body tethering (VBT) when **all** the following are present:
      i. Cobb measurement between 35 and 65 degrees;
      ii. Bracing has failed, is not tolerated, or is otherwise unsuitable; **and**
      iii. Skeletal immaturity with meaningful growth remaining; **or**
   c. In early-onset disease with a curve exceeding 40 degrees and substantial residual growth, a growth-preserving construct (traditional growing rods or magnetically controlled growing rods).

DESCRIPTION

The cervical and lumbar-sacral spine are common sites of degenerative, structural, and traumatic disease that can compress the spinal cord and nerve roots or destabilize the spinal column. When these conditions produce pain, neurologic impairment, or functional limitation that does not respond to appropriate non-surgical treatment, or when urgent neurologic compromise is present, surgical intervention may be used to relieve pressure on neural structures (decompression), stabilize abnormal motion (fusion/arthrodesis), replace a diseased disc (arthroplasty), or correct structural deformity (osteotomy or scoliosis correction).

Common Clinical Conditions

- Cauda equina syndrome (CES) is a surgical emergency caused by severe compression of the bundle of nerve roots at the base of the spine, producing new bowel and/or bladder dysfunction, saddle anesthesia, and frequently bilateral lower-extremity pain, numbness, or weakness. CES requires urgent decompression and is exempt from conservative care and other elective requirements.

- Degenerative disc disease (DDD) is the age-related deterioration of an intervertebral disc, with loss of disc height, dehydration, bulging, or herniation. Although commonly associated with aging, surgical treatment is generally considered only when degeneration is associated with nerve compression, instability, or other clinically significant pathology that correlates with symptoms.
- A herniated disc is displacement of the inner disc material beyond its normal boundary, which may press on a nerve root or the spinal cord.
- Myelopathy is dysfunction of the spinal cord itself from compression. Signs include problems with balance or walking, loss of hand dexterity, overactive reflexes, and in severe cases bowel or bladder dysfunction. It is generally progressive and typically warrants more urgent evaluation and treatment than isolated radiculopathy.
- Pseudarthrosis (failed fusion) is the failure of a prior fusion to heal into solid bone, which can cause recurrent pain and instability and may warrant a repeat operation.
- Scoliosis is an abnormal lateral and rotational curvature of the vertebral column. Adolescent idiopathic scoliosis is the most common form of idiopathic scoliosis. Severe progressive thoracic deformities may be associated with cardiopulmonary compromise. Diagnosis is made clinically and radiographically.
    - The curve is measured by the Cobb angle, which is the angle formed between intersecting lines drawn perpendicular to the top of the vertebrae of the curve and the bottom vertebrae of the curve.
    - The Risser sign measures remaining spinal growth by progressive anterolateral to posteromedial ossification. Risser sign ranges from 0 (no ossification) to 5 (full bony fusion of the apophysis). Immature patients will have 0% to 25% ossification (Risser grade 0 or 1), while 100% ossification (Risser grade 5) indicates maturity with no spinal growth remaining. Children may progress from a Risser grade 1 to grade 5 over a brief (eg, 2-year) period.
- Radiculopathy refers to symptoms caused by compression or irritation of a single nerve root. Symptoms typically include pain, numbness, tingling, or weakness that follows the path of that nerve into the arm (cervical) or leg (lumbar).
- Segmental instability is abnormal, excessive movement between two (2) vertebrae that may be demonstrated by dynamic imaging studies (e.g., flexion-extension radiographs) and can cause pain or neural compromise.
- Spinal stenosis is narrowing of the spinal canal or the openings where nerves exit (foramina), most often from degeneration, that can compress neural structures.
- Spondylolisthesis is forward (or backward) slippage of one vertebra relative to the one below it, which may narrow the canal and destabilize the segment.
- Spondylosis is general degenerative "wear-and-tear" arthritis of the spine, including bone spurs (osteophytes) and joint degeneration that can narrow the spaces around the spinal cord and

nerves.

Cervical Spine Procedures

- Cervical arthrodesis is the permanent joining of two or more vertebrae so they heal into a single bone, eliminating motion at the painful or unstable segment. It is used for instability, deformity, or to stabilize the spine after decompression or removal of disc or bone.
- Cervical corpectomy involves removal of all or part of a vertebral body and adjacent discs to decompress the spinal cord or nerve roots when compression is located behind the vertebral body itself, such as from tumor, infection, trauma, or extensive spondylosis. Because structural bone is removed, fusion and reconstruction are required.
- Cervical disc arthroplasty (CDA), also known as artificial/cervical disc replacement, is a motion-preserving alternative to ACDF for selected one- or two-level disc disease between C3 and C7. The diseased disc is removed and replaced with an FDA-approved artificial disc intended to decompress the nerves or spinal cord while maintaining cervical motion. Appropriate candidates require skeletal maturity and suitable anatomy, including adequate bone quality and the absence of significant deformity, instability, or facet arthropathy.
- Anterior cervical discectomy and fusion (ACDF) is the most established operation for symptomatic cervical disc disease. Through the front of the neck, the surgeon removes the diseased disc and any associated bone spurs to decompress the nerves or spinal cord, then fuses the segment to restore height, alignment, and stability.
- Posterior cervical decompression, with or without fusion, relieves pressure on the spinal cord or nerve roots through the back of the neck by removing bone or ligament. Techniques include laminectomy (removal of the lamina), laminoforaminotomy (enlargement of the nerve root exit), and laminoplasty (reshaping or hinging the lamina to expand the spinal canal while preserving motion). Fusion may be added when the segment is unstable or expected to become unstable.
- Combined anterior and posterior decompression and fusion uses both front and back surgical approaches and is generally reserved for complex disease, such as multilevel compression or deformity, when a single approach cannot adequately decompress or stabilize the spine.

Lumbar-Sacral Spine Procedures

- Lumbar arthrodesis permanently joins lumbar vertebrae to eliminate painful or unstable motion. Indications include degenerative spondylolisthesis, segmental instability, deformity, and recurrent disc herniation requiring stabilization. Fusion may be performed alone or combined with decompression through anterior, posterior, or lateral surgical approaches depending on the clinical situation.
- Single-level lumbar fusion, with or without decompression, treats a structurally confirmed abnormality at a single motion segment, such as spondylolisthesis associated with instability or abnormal segmental motion, or, in selected circumstances, carefully evaluated chronic axial low back pain associated with single-level degenerative pathology.

- Repeat (revision) lumbar fusion at the same level may be performed when a previous fusion has failed because of hardware failure, hardware malposition, or a symptomatic non-union (pseudarthrosis) confirmed on imaging.
- Lumbar decompression relieves pressure on the nerve roots or cauda equina in individuals with neurogenic claudication or radiculopathy caused by spinal stenosis. Techniques include laminectomy, laminotomy, foraminotomy, and facetectomy to enlarge the spinal canal or nerve root openings.
- Lumbar discectomy or microdiscectomy removes the herniated portion of a disc that is compressing a nerve root, typically for radiculopathy that has not improved with conservative management or, more urgently, for cauda equina syndrome or severe or progressive weakness. The term "microdiscectomy" refers to the use of magnification and smaller surgical exposures.
- Lumbar osteotomy involves surgical cutting and realignment of one or more vertebrae to correct a fixed spinal deformity, such as flatback deformity or fixed sagittal imbalance, that impairs standing, walking, or horizontal gaze. It is typically performed as part of a larger spinal reconstruction.
- Pediatric scoliosis surgery corrects spinal curvature in children and adolescents. Surgical options include posterior instrumented spinal fusion for larger curves, growth-preserving instrumentation such as traditional or magnetically controlled growing rods for early-onset scoliosis with substantial growth remaining, and vertebral body tethering in appropriately selected skeletally immature patients.
- Percutaneous lumbar disc decompression / discectomy are needle-based techniques that remove or shrink disc material through a small puncture under imaging guidance, including automated percutaneous lumbar discectomy (e.g., Nucleotome), mechanical percutaneous discectomy (e.g., Dekompressor), percutaneous laser disc decompression (PLDD), nucleoplasty/plasma (coblation) disc decompression, and targeted disc decompression.

<u>Cross-Cutting Concepts in the Criteria</u>

- Conservative (non-surgical) management for non-urgent conditions aims to relieve pain, improve or restore function, and allow an appropriate trial of non-operative treatment before surgical intervention is considered. Conservative therapy may include a documented trial of supervised physical therapy and pain management (e.g., medications, interventional injections, and non-pharmacologic measures). This requirement is waived for urgent or emergent presentations, such as cauda equina syndrome, progressive neurologic deficit, significant motor weakness, myelopathy with cord compression, or instability/compression related to trauma, tumor, or infection.
- Imaging concordance requires that advanced imaging (MRI, CT, or CT myelogram), supplemented by X-rays when needed, demonstrate a structural abnormality that correlates with the patient's symptoms and physical examination findings. Surgery is not supported when imaging findings do not correlate with the clinical presentation.

- Nicotine abstinence is required for fusion procedures because nicotine is associated with impaired bone healing and increased risk of non-union. Fusion criteria generally require the patient to be nicotine-free, which may be confirmed through cotinine testing. This requirement does not apply to urgent or emergent fusion procedures when delaying treatment would compromise the patient's condition.

Standardized Spine Assessments

- modified Japanese Orthopaedic Association (mJOA) score grades cervical myelopathy severity (motor, sensory, and bladder function) and is used to categorize myelopathy as mild, moderate, or severe, and informs urgency and timing of decompression.
- Neck Disability Index (NDI) is the cervical counterpart of the ODI, a 10-item questionnaire scored 0–100% measuring how neck pain limits daily function. It is used to document disability for cervical conditions and procedures (e.g., ACDF).
- Numeric Rating Scale (NRS) is a simple 0–10 verbal or written pain rating, often used interchangeably with the VAS to document pain intensity at rest and with activity.
- Oswestry Disability Index (ODI) is a 10-item questionnaire scored 0–100% that measures how low back pain limits daily activities (lifting, walking, sitting, sleep, personal care). It is the most widely used measure of lumbar-related disability, documenting functional impairment and improvement.
- Roland-Morris Disability Questionnaire (RMDQ) is a 24-item yes/no measure of low back pain–related disability, an alternative to the ODI for tracking functional limitation.
- Visual Analog Scale (VAS) is a patient-reported pain score, typically marked on a 0–100 mm line or rated 0–10, used to quantify back, neck, arm, or leg pain before and after treatment.

SUPPORTIVE LITERATURE

Cervical Arthroplasty

Early pivotal United States Food and Drug Administration (FDA) Investigational Device Exemption (IDE) randomized controlled trials (RCTs) demonstrated that cervical disc arthroplasty (CDA) preserves segmental motion and provides clinical outcomes comparable to anterior cervical discectomy and fusion (ACDF) in appropriately selected patients with symptomatic cervical degenerative disc disease. Evidence from single-level and multilevel studies supports durable improvements in pain, disability, and neurologic outcomes (Heller 2009; Zigler 2013; Burkus 2014).

Kim et al (2021) reported the 10-year outcomes from the prospective multicenter Mobi-C FDA IDE clinical trial in patients undergoing one- or two-level CDA. Patients maintained significant improvement from baseline in NDI, neck and arm pain, neurologic function, and segmental range of motion (ROM) through 10 years, with only two subsequent surgeries reported after 7 years. The authors concluded that CDA remained a safe and effective treatment for one- and two-level cervical degenerative disc disease through 10 years of follow-up.

Sasso et al (2024) reported 20-year outcomes from the prospective randomized FDA IDE trial comparing BRYAN CDA with ACDF in 47 patients with single-level cervical radiculopathy. Follow-up was available for 91.3% of participants, with both groups demonstrating sustained, statistically significant improvement in NDI and VAS neck and arm pain from baseline. There was no significant difference between CDA and ACDF in 20-year NDI, VAS neck pain, or VAS arm pain scores. Reoperation was reported in 10.0% of CDA patients and 41.7%, ACDF patients (P = 0.039), with no arthroplasty device failures requiring index-level device reoperation. The authors concluded that both CDA and ACDF were effective treatments for cervical radiculopathy, with CDA demonstrating lower reoperation rates over long-term follow-up.

Foley et al (2024) reported the corresponding 20-year radiographic outcomes from the BRYAN FDA IDE trial. The study found that CDA maintained index-level ROM (P = 0.952) and preserved greater overall cervical ROM than ACDF (47.8° vs. 33.4°, P = 0.005). CDA was also associated with significantly lower rates of adjacent-segment degeneration (P < 0.005) and adjacent-level ossification (P < 0.001).

Yakdan et al (2025) performed a systematic review and meta-analysis of 25 RCTs (35 studies) comparing CDA (n=2,449) and ACDF (n=2,081) for degenerative disc disease. CDA demonstrated higher rates of neurological and overall success, lower rates of adjacent level disease and reoperation, greater ROM at the operated level, and higher rates of heterotopic ossification. Operative times were significantly longer than with ACDF. Despite identified study limitations (e.g., inclusion of myelopathic patients and variations in follow-up between treatment groups contributed to heterogeneity among studies), the authors concluded the study found CDA showed comparable or potentially more favorable outcomes in achieving overall and neurological success, with a lower incidence of adjacent-level degeneration, and reoperation rates, but longer operative time.

Lumbar Discectomy / Microdiscectomy

Overall, in patients with lumbar radiculopathy with disc herniation who receive discectomy, there is sufficient evidence to support the use of discectomy in patients who have not responded to usual care for 6 weeks, but the net benefit is uncertain because of the lack of a robust RCT comparing discectomy with a comprehensive conservative treatment program. The evidence is limited by a lack of high-quality trials. In most trials, a high percentage of patients in the conservative care group crossed over to surgery.

Weinstein et al (2006) reported on SPORT, a moderately-large trial that compared discectomy to non-operative care in patients with lumbar disc herniation and included both a randomized and a non-randomized component. The RCT included 501 patients randomized to discectomy or to usual care. Discectomy was performed by the open technique, and, in some cases, the medial border of the superior facet joint was removed. Crossover was allowed during the trial; 107 of the 245 patients assigned to usual care underwent surgery, and 140 of the 245 patients assigned to surgery underwent surgery. The main outcomes were changes from baseline in the bodily pain and physical function subscales of the SF-36, and the modified Oswestry Disability Index (ODI) measured at time points up to two years. Secondary outcomes included self-reported improvement, work status, satisfaction with care, and a symptom severity measure (Sciatica Bothersomeness Index). For the

primary outcomes evaluated using ITT analysis, improvements in ODI scores were superior for the surgery group at three months, but, at the one- and two-year follow-ups, there were no significant group differences on either primary outcome. For secondary outcomes, there were significant improvements for the surgery group on the Sciatica Bothersomeness Index at all time points, and satisfaction with care was superior for the surgery group at three (3) months, but not at longer time points. A secondary analysis was performed on a treatment-received basis, and this analysis showed significantly greater improvements for the surgery group at all time points. The estimated treatment effects for the SF-36 bodily pain and physical function subscales were 15.0 and 17.5, respectively, on a 0-to-100 scale. The estimated change in the ODI score was -15.0 on a 0 to 100 scale.

Clark et al (2020) published a systematic review assessing the efficacy, safety, and cost of surgical versus nonsurgical management of lumbar radiculopathy. The systematic review included seven RCTs (5 discectomy and/or microdiscectomy; 2 percutaneous disc decompression with or without coblation) published between January 2007 and April 2019. Results revealed that surgery reduced VAS-leg pain scores as compared to nonsurgical management at up to week 26; however, the differences in these scores did not persist at 1 year or later. Regarding function and disability, the evidence was mixed with minimal differences between surgical and nonsurgical management at 2 years. Comparable improvements in quality of life, neurologic symptoms, and return to work were seen with no surgical deaths and infrequent surgical morbidity reported. The authors of the systematic review rated 5 included RCTs as having a high risk of bias due to inadequate methods of randomization or allocation concealment, lack of blinding, crossover, and attrition.

Bailey et al (2020) published a prospective RCT from a single Canadian site involving 128 patients with persistent sciatica lasting 4 to 12 months and lumbar disc herniation. Enrolled patients were randomly assigned to undergo microdiscectomy or receipt of 6 months of standardized nonoperative care (education regarding day-to-day functioning, activity and exercise, oral analgesics, active physiotherapy, epidural glucocorticoid injections) followed by surgery if necessary. Follow-up was performed at 6 weeks, 3 months, 6 months, and 1 year after enrollment. Results revealed that the surgical group experienced a significant reduction in the VAS-leg pain intensity score at 6 months as compared to the nonsurgical group. At 1 year, a continued reduction in leg-pain intensity, as well as ODI score and pain, was observed in the surgical group. There was a potential impact on external validity with this trial as both surgeons and patients may have been less inclined to undertake nonsurgical care if severe sciatica was present. Additionally, the generalizability of this study may be diminished due to its single-center nature and up to 20% of the data for the primary outcome were absent. A total of 22 patients from the nonsurgical group ultimately crossed over to surgery due to intractable sciatic pain.

Smoking

Tobacco use is considered a risk factor for poor healing and is associated with non-union. It is well-established that smoking is a preventable cause of morbidity and mortality. Lumbar fusion is in most situations an elective surgery; it is strongly recommended that individuals be in the best physical condition prior to undergoing surgery.

Cotinine, the primary metabolite of nicotine, is currently regarded as the best biomarker of tobacco

smoke exposure. Measuring cotinine is preferable to measuring nicotine because cotinine persists longer in the body. Non-smokers exposed to typical levels of second-hand smoke have serum cotinine levels lower than one ng/ml, with heavy exposure to second-hand smoke producing levels in the 1-10 ng/ml range. Active smokers almost always have levels higher than 10 ng/ml and sometimes higher than 500 ng/ml. Therefore, non-smoking is defined as a serum cotinine level of less than or equal to 10 ng/ml.

Khalid et al (2022) evaluated 31,935 patients undergoing single-level lumbar fusion , including active smokers, patients receiving smoking cessation therapy, and patients without a smoking history.. Patients undergoing smoking cessation therapy had lower odds of any postoperative complication compared with active smokers (OR 0.86, 95 % CI: 0.80 to 0.93) The authors concluded smoking cessation therapy within 90 days of surgery decreased the likelihood of all-cause post-operative complications. However, there were no between-group differences in the likelihood of pseudarthrosis, revision surgery, or re-admission within 90 days.

In a retrospective database study, Connor et al (2022) 703,051 patients who underwent elective spine surgery with discectomy, fusion, or decompression for degenerative cervical or thoracolumbar spine disorders. After adjustment for patient and hospital characteristics, tobacco use was independently associated with re-admission at 90 days (OR 1.05, 95 % CI: 1.03 to 1.07, $p < 0.0001$), but not 30 days (OR 1.02, 95 % CI: 1.00 to 1.05, $p = 0.045$). Postoperative infection was the most common reason for both 30- and 90-day readmissions. The authors concluded that tobacco use is a known risk factor for adverse health events and should be considered when selecting patients for spine surgery

Annular Repair Following Spinal Surgery

Thome et al (2018) conducted a randomized controlled trial at 21 European centers to determine whether adding a bone-anchored annular closure device (ACD) to limited microdiscectomy reduced reherniation and reoperation rates and improved overall success compared with microdiscectomy alone. A total of 554 patients were randomized to the ACD group (n=267) or control (n=283). Eligible patients were 21 to 75 years of age with imaging-confirmed single-level lumbar disc herniation between L1 and S1, disc height of 5 mm or greater, and failure of at least 6 weeks of nonsurgical treatment. At 2 years, symptomatic reherniation was lower in the ACD group (12% vs. 25%; p<.001), as was reoperation (5% vs. 13%; p=.0001), with no difference in all-cause serious adverse events between groups.

Longer-term follow-up reinforced these findings. At 3 years, ACD discectomies resulted in fewer symptomatic reherniations (15% vs. 30%) and fewer reoperations (11% vs. 19%), with modest improvements in disability and quality-of-life scores favoring the ACD group (Kienzler, 2019). Four-year reoperation rates were 14.4% with ACD versus 21.1% with control (Nanda et al., 2019). At 5 years, outcomes remained lower in ACD patients, with reduced risk of symptomatic reherniation (18.8% vs. 31.6%; p<.001) and reoperation (16.0% vs. 22.6%; p=.03) (Thome, 2021). A notable limitation of this body of evidence is that investigators were not blinded to treatment assignment, and only patients at select sites were blinded.

Miller LE et al (2020) published a systematic review and meta-analysis of the annular closure device in patients at high risk for lumbar disc reherniation, including four trials (two randomized controlled trials). The 2018 Thome trial was the only study to demonstrate a statistically significant reduction in symptomatic reherniation or reoperation at 2 years. The other three trials showed nonsignificant reductions for both outcomes. Overall, the meta-analysis favored use of the annular device for post-discectomy patients with large annular defects.

Stabilization/Distraction Implants

Schmidt et al. (2018) reported results of a randomized controlled trial in 225 patients with moderate-to-severe lumbar spinal stenosis and back pain, with or without spondylolisthesis, who underwent open microsurgical decompression with interlaminar stabilization using the coflex device (n=110) or decompression alone (n=115). At 24 months, composite clinical success was significantly higher in the coflex group than in the decompression-alone group (58.4% vs. 41.7%; p=.017), primarily driven by fewer epidural steroid injections (4.5% vs. 14.8%; p=.010). No statistically significant differences were observed in ODI success among patients censored for secondary interventions (75.6% vs. 70.4%; p=.47), overall ODI success (55% vs. 44%; p=.091), or other clinical outcomes, including ZCQ and VAS scores. Limitations included potential bias, inconsistent reporting of intention-to-treat analyses, and incomplete outcome reporting, with primary outcome data available for 204 of 254 randomized patients. The impact of the missing data on study results was not reported.

Li et al (2023) conducted a systematic review and meta-analysis to investigate evidence for the comparison of lumbar dynamic stabilization device Coflex with posterior lumbar fusion for lumbar spinal stenosis. A total of 26 studies were included and relational databases were searched up to October 2022. Lumbar dynamic stabilization device Coflex had shorter operation time (mean P <0.00001), less intraoperative blood loss (P < 0.00001), and shorter hospital stays (P < 0.00001). The Japanese Orthopedic Association (JOA) score and ODI score were higher in the Coflex group during early follow-up. There was no significant difference between the two groups with the extension of follow-up time. Moreover, the Coflex group had a lower VAS score than fusion treatment (P < 0.00001). Finally, the Coflex group had lower total complications rate (P= 0.03), lower ASD rate (P=0.001), and higher range of motion (P < 0.00001), but there was no significant difference in reoperation rate and internal fixation problems rate.

Xin et al (2023) conducted a meta-analysis of eight randomized controlled trials including 852 patients to evaluate the safety and effectiveness of interspinous spacers compared with decompressive surgery for lumbar spinal stenosis. Outcomes were generally comparable between groups with respect to hospital stay, blood loss, spinous process fracture, disc height loss, VAS pain scores, ODI scores, and Zurich Claudication Questionnaire symptom severity scores. However, interspinous spacer implantation was associated with a higher rate of reoperation than decompressive surgery. Limitations included the relatively small, pooled population and limited long-term follow-up. The authors concluded that additional well-designed studies with longer follow-up are needed to further evaluate the efficacy and safety of interspinous spacers.

Disc Herniation/Degenerative Disc Disease (DDD)

Current evidence, which includes a large, multi-center, randomized, controlled trial (RCT) by Weinstein (2006) known as Spine Patient Outcomes Research Trial (SPORT), supports that surgical treatment with discectomy improves outcomes for lumbar disc herniation with radiculopathy. However, there is no evidence to support that the addition of spinal fusion to discectomy improves outcomes in patients with the sole indication of lumbar disc herniation without instability.

Spinal Stenosis with Spondylolisthesis

The SPORT RCT (Weinstein 2007 and 2009) compared surgical and nonsurgical treatment for lumbar degenerative spondylolisthesis. All patients had neurogenic claudication or radicular leg pain associated with neurologic signs, spinal stenosis shown on cross-sectional imaging, and degenerative spondylolisthesis shown on lateral radiographs, with symptoms persisting for at least 12 weeks. There were 304 patients in a randomized cohort and 303 patients in an observational cohort. About 40% of the randomized cohort crossed over in each direction by two years of follow-up. At the four-year follow-up timepoint, 54% of patients randomized to non-operative care had undergone surgery. Five percent of the surgically treated patients received decompression only, and 95% underwent decompression with fusion. Analysis was by the treatment that was received, due to the high percentage of crossovers. This analysis, controlled for baseline factors, showed a significant advantage for surgery at up to four years of follow-up for all primary and secondary outcome measures.

Scoliosis

Treatment of scoliosis currently depends on three factors: etiology (idiopathic, congenital, secondary), curve severity (Cobb angle), and the remaining skeletal growth at presentation. Progression risk rises with larger curves and greater skeletal immaturity, with curves in the 25°–40° range in a patient with substantial growth remaining (e.g., low Risser/Sanders stage, open triradiate cartilage) carries a meaningfully elevated risk of progression. Since large curves, particularly thoracic curves, may progress into adulthood and large thoracic deformities can compromise pulmonary function, and because untreated scoliosis is associated with increased back pain in adulthood, surgical correction with spinal fusion is generally recommended once curves progress to approximately 45°–50° or more.

Kolenko et al (2020) states that children who have curves approaching 50° should be referred to an orthopedic surgeon for consultation. The goals of surgical treatment include preventing curve progression while obtaining spinal correction, realignment, and multilevel fusion. Corrective surgeries most frequently follow a posterior approach, but anterior and a combination of anterior and posterior surgery are dependent on surgeon preference and curve type. Current techniques aim to either fuse the spine or modulate growth. Both posterior and anterior spinal fusions use a combination of implants to provide surgical correction and result in 15% to 48% Cobb angle improvement on the coronal plane.

Abdelaal et al (2025) published a systematic review and meta-analysis comparing anterior vertebral body tethering (VBT) with posterior spinal fusion (PSF) for adolescent idiopathic scoliosis. Ten comparative cohort studies comprising 1168 patients were included. At 2-year follow-up, VBT was

associated with less radiographic correction than PSF in the main thoracic curve and proximal thoracic curve, while no significant differences were observed in main thoracic Cobb angle overall or in lumbar curve correction. VBT also demonstrated perioperative advantages, including significantly shorter operative time, less blood loss, and shorter hospital stay. However, VBT carried a significantly higher revision surgery risk compared with PSF. Study authors concluded that while VBT offers meaningful perioperative and recovery advantages and comparable short-term patient-reported outcomes in selected skeletally immature patients, it results in less consistent radiographic correction and substantially higher revision rates than PSF.

Dynamic Stabilization Systems/Devices

The available evidence does not demonstrate that spinal dynamic stabilization devices improve health outcomes compared with the established standard of instrumented fusion. The highest-quality data, including a multicenter double-blind randomized trial (Meyer 2022), show outcomes comparable to fusion without proven long-term superiority. The evidence is largely confined to the lumbar spine and is limited by short follow-up, heterogeneity, and publication bias. No clinical practice guideline endorses dynamic stabilization as superior to or a substitute for fusion. Larger randomized trials with longer follow-up are needed before these devices can be recommended over the established fusion standard.

Interspinous Fixation Devices (IFDs)

There is a lack of high-quality comparative evidence on the efficacy of IFDs in combination with interbody fusion. Reported risks include, while a potential benefit is a reduction in adjacent segment degeneration. Randomized trials with longer follow-up are needed to evaluate the risks and benefits following use of IFDs compared with the established standard (pedicle screw with rod fixation).

PROFESSIONAL GUIDELINE(S)

Cervical Arthroplasty (Replacement)

The North American Spine Society (NASS) coverage policy for Cervical Artificial Disc Replacement (2015; revised Feb 2024) indicates that cervical artificial disc replacement may be indicated for the following diagnoses with qualifying criteria, when appropriate:

- Radiculopathy related to nerve root compression from one- or two- level degenerative disease (either herniated disc or spondylotic osteophyte) from C3-7 in the following scenarios:
    - Persistent symptoms despite at least 6 weeks of nonoperative management.
    - Progressive or functionally limiting weakness correlating with the compressed nerve root.
    - Inability to perform normal work duties or necessary activities of daily living because of severity of symptoms, despite nonoperative management.
- Myelopathy or myeloradiculopathy related to central spinal stenosis from one- or two-level degenerative disc disease from (either herniated disc or spondylotic osteophyte) C3-4.
- There is no significant evidence at this time to support the following:

- Its use for 3 or more levels.
- It's use for isolated axial neck pain. Neck pain along with radiculopathy/myeloradiculopathy, is not an exclusionary criterion. There is early evidence for use in treatment of adjacent segment disease following an index fusion.

Lumbar Arthrodesis

In 2011, the North American Spine Society (NASS) issued evidence-based guidelines on the diagnosis and treatment of degenerative lumbar spinal stenosis. The guidelines stated that patients with mild symptoms of lumbar spinal stenosis are not considered surgical candidates; however, decompressive surgery was suggested to improve outcomes in patients with moderate-to-severe symptoms of lumbar spinal stenosis (grade B recommendation). NASS also indicated that current evidence was insufficient to recommend for or against the placement of interspinous process spacing devices to treat spinal stenosis. A 2013 update of this guideline from the Degenerative Lumbar Spinal Stenosis Work Group of the NASS notes the same recommendations.

In July 2018, the National Institute for Health and Care Excellence (NICE) provided evidence-based recommendations on transaxial interbody lumbosacral fusion for low back pain in adults. The recommendation, based on a literature review conducted in December 2017, states, "Evidence on the safety of transaxial interbody lumbosacral fusion for severe chronic low back pain shows that there are serious but well-recognized complications. Evidence on efficacy is adequate in quality and quantity. Therefore, this procedure may be used provided that standard arrangements are in place for clinical governance, consent and audit. This procedure should only be done by a surgeon with specific training in the procedure, who should carry out their initial procedures with an experienced mentor."

Lumbar Decompression

In 2022, NASS issued coverage policy recommendations related to lumbar decompression and included the following diagnoses with qualifying criteria: Lumbar spinal stenosis (primary or recurrent); Synovial facet cyst associated with either radiculopathy or neurogenic claudication; cauda equina syndrome caused by prominent compression of the thecal sac in the lumbar spine, with resultant saddle anesthesia, new onset loss of bowel/bladder function, or new onset of lower extremity neurologic deficits not explained by a more proximal lesion; tumor; fracture; epidural/subdural hematoma, infection, degenerative/isthmic spondylolisthesis; or additional diagnoses requiring non-decompressive laminectomies/laminotomies or other dorsal approaches.

Lumbar Discectomy

The North American Spine Society (NASS, 2019) coverage policy for lumbar discectomy recommends that primary or recurrent lumbar disc herniation with radiculopathy indicated when both criteria are met:

- Lumbar radiculopathy is present, and a correlative lesion is present on advanced imaging.
- Presence of symptoms for at least 6 weeks and inability to tolerate or failure to respond to 4 weeks of nonsurgical care, including but not limited to physical therapy, chiropractic treatment,

and/or fluoroscopic-guided epidural steroid injections

Bone-Anchored Annular Closure Device (ACD)

In 2025, the International Society for the Advancement of Spine Surgery (ISASS) updated recommendations for bone-anchored annular closure device as follows: "Based on the accumulating clinical evidence, ISASS reiterates its position that in patients with symptomatic lumbar disc herniation (LDH) with radiculopathy undergoing primary discectomy with large (≥6 mm wide) annular defects, bone-anchored annular closure may be used to sustain the treatment benefits of discectomy by reducing the risk of recurring LDH and the need for reoperation." ISASS recommends consideration of annular closure devices in:

- "Symptomatic LDH with radiculopathy, confirmed by clinical history, physical examination, and imaging.
- Single-level disc herniation L4 to L5 or L5 to S1.
- Moderately preserved disc height: ≥5 mm posterior disc height.
- Large annular defect (between 4 and 6 mm tall and between 6 and 10 mm wide) visualized intraoperatively after discectomy."

Percutaneous Lumbar Discectomy / Disc Decompression

In 2022, the American Society of Pain and Neuroscience (ASPN) (Deer 2022) published a consensus guideline outlining best practices for minimally invasive lumbar spinal stenosis treatment. The following recommendation was provided with regard to the use of percutaneous image-guided lumbar decompression: "Percutaneous image- guided decompression should be considered for the treatment of symptomatic lumbar spinal stenosis with the presence of neurogenic claudication, with less than or equal to a grade 2 spondylolisthesis, and with a ligamentum flavum hypertrophy greater than or equal to 2.5mm." Grade A; Level of certainty high; Level of evidence 1-A.

Pre-operative Optimization

Harrop et al (2021) published the Congress of Neurological Surgeons (CNS) evidence-based guideline for preoperative surgical risk assessment, with the following findings

- Individuals undergoing spinal fusion surgery who are active smokers should be counseled regarding the increased risk of reoperation. (Grade B)
- There is insufficient evidence that cessation of smoking before spine surgery decreases the risk of reoperation; however, patients should be counseled to abstain from smoking before and after spinal fusion surgery. (Grade Insufficient)
- Diabetic individuals undergoing spine surgery should have a preoperative HbA1c test and be counseled regarding the increased risk of reoperation or infection when HbA1c is greater than 7.5%. (Grade B)
- There is conflicting evidence regarding the association between elevated BMI and reoperation or surgical site infection; however, patients with elevated BMI should be counseled regarding the

potential increased risk. (Grade Insufficient)

According to the 2025 NASS clinical guidelines for antithrombotic therapies for adults undergoing spine surgery:

- There is fair evidence suggesting that chemoprophylaxis is not associated with increased hemorrhagic complication rates in patients undergoing elective spine surgery. (Grade B)
- It is suggested that the use of chemoprophylaxis is not associated with an increased hemorrhagic complication rate in patients undergoing surgery for spine trauma. (Grade B)

Stabilization / Distraction Implants

In 2025, the North American Spine Society (NASS) published three coverage recommendations for interspinous devices: interspinous decompression devices, interspinous devices without fusion and without decompression, and interspinous fusion devices.

REGULATORY STATUS

The U.S. Food and Drug Administration (FDA) regulates spinal implants and spinal fixation and instrumentation used during spine procedures as medical devices. All require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2026 Oct 1]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most serious type of recalls. Available from: https://www.fda.gov/medical-devices/medical-device-safety/medical-device-recalls-and-early-alerts [accessed 2026 Oct 1]

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
22207	Osteotomy of spine, posterior or posterolateral approach, 3 columns, 1 vertebral segment (e.g., pedicle/vertebral body subtraction); lumbar
22214	Osteotomy of spine, posterior or posterolateral approach, 1 vertebral segment; lumbar

22224	Osteotomy of spine, including discectomy, anterior approach, single vertebral segment; lumbar
22526 (E/I)	Percutaneous intradiscal electrothermal annuloplasty, unilateral or bilateral including fluoroscopic guidance; single level
22533	Arthrodesis, lateral extracavitary technique, including minimal discectomy to prepare interspace (other than for decompression); lumbar
22548	Arthrodesis, anterior transoral or extraoral technique, clivus-C1-C2 (atlas-axis), with or without excision of odontoid process
22551	Arthrodesis, anterior interbody, including disc space preparation, discectomy, osteophytectomy and decompression of spinal cord and/or nerve roots; cervical below C2
22554	Arthrodesis, anterior interbody technique, including minimal discectomy to prepare interspace (other than for decompression); cervical below C2
22558	Arthrodesis, anterior interbody technique, including minimal discectomy to prepare interspace (other than for decompression); lumbar
22586	Arthrodesis, pre-sacral interbody technique, including disc space preparation, discectomy, with posterior instrumentation, with image guidance, includes bone graft when performed, L5-S1 interspace
22590	Arthrodesis, posterior technique, craniocervical (occiput-C2)
22595	Arthrodesis, posterior technique, atlas-axis (C1-C2)
22600	Arthrodesis, posterior or posterolateral technique, single interspace; cervical below C2 segment
22612	Arthrodesis, posterior or posterolateral technique, single level; lumbar (with lateral transverse technique, when performed)
22630	Arthrodesis, posterior interbody technique, including laminectomy and/or discectomy to prepare interspace (other than for decompression), single interspace; lumbar
22633	Arthrodesis, combined posterior or posterolateral technique with posterior interbody technique including laminectomy and/or discectomy sufficient to prepare interspace (other than for decompression), single interspace and segment; lumbar
22800	Arthrodesis, posterior, for spinal deformity, with or without cast; up to 6 vertebral segments
22802	Arthrodesis, posterior, for spinal deformity, with or without cast; 7 to 12 vertebral segments

22804	Arthrodesis, posterior, for spinal deformity, with or without cast; 13 or more vertebral segments
22808	Arthrodesis, anterior, for spinal deformity, with or without cast; 2 to 3 vertebral segments
22810	Arthrodesis, anterior, for spinal deformity, with or without cast; 4 to 7 vertebral segments
22812	Arthrodesis, anterior, for spinal deformity, with or without cast; 8 or more vertebral segments
22843	Posterior segmental instrumentation (eg, pedicle fixation, dual rods with multiple hooks and sublaminar wires); 7 to 12 vertebral segments (List separately in addition to code for primary procedure)
22849	Reinsertion of spinal fixation device
22850	Removal of posterior nonsegmental instrumentation (e.g., Harrington rod)
22852	Removal of posterior segmental instrumentation
22855	Removal of anterior instrumentation
22856	Total disc arthroplasty (artificial disc), anterior approach, including discectomy with end plate preparation (includes osteophytectomy for nerve root or spinal cord decompression and microdissection); single interspace, cervical
22857	Total disc arthroplasty (artificial disc), anterior approach, including discectomy to prepare interspace (other than for decompression), single interspace, lumbar
22861	Revision including replacement of total disc arthroplasty (artificial disc), anterior approach, single interspace; cervical
22862	Revision including replacement of total disc arthroplasty (artificial disc), anterior approach, single interspace; lumbar
62287 (E/I)	Decompression, percutaneous, of nucleus pulposus of intervertebral disc, any method utilizing needle-based technique to remove disc material under fluoroscopic imaging or other form of indirect visualization, with discography and/or epidural injection(s) at the treated level(s), when performed, single or multiple levels, lumbar.
62330	Decompression, percutaneous, with partial removal of the ligamentum flavum, including laminotomy for access, epidurography, and imaging guidance (i.e., CT or fluoroscopy), bilateral; one interspace, lumbar
62380	Endoscopic decompression of spinal cord, nerve root(s), including laminotomy, partial facetectomy, foraminotomy, discectomy and/or excision of herniated

	intervertebral disc, 1 interspace, lumbar
63001	Laminectomy with exploration and/or decompression of spinal cord and/or cauda equina, without facetectomy, foraminotomy or discectomy (e.g., spinal stenosis), 1 or 2 vertebral segments; cervical
63005	Laminectomy with exploration and/or decompression of spinal cord and/or cauda equina, without facetectomy, foraminotomy or discectomy (e.g., spinal stenosis), 1 or 2 vertebral segments; lumbar, except for spondylolisthesis
63011	Laminectomy with exploration and/or decompression of spinal cord and/or cauda equina, without facetectomy, foraminotomy or discectomy (e.g., spinal stenosis), 1 or 2 vertebral segments; sacral
63012	Laminectomy with removal of abnormal facets and/or pars interrticularis with decompression of cauda equina and nerve roots for spondylolisthesis, lumbar (Gill type procedure)
63015	Laminectomy with exploration and/or decompression of spinal cord and/or cauda equina, without facetectomy, foraminotomy or discectomy (e.g., spinal stenosis), more than 2 vertebral segments; cervical
63017	Laminectomy with exploration and/or decompression of spinal cord and/or cauda equina, without facetectomy, foraminotomy or discectomy (e.g., spinal stenosis), more than 2 vertebral segments; lumbar
63020	Laminotomy (hemilaminectomy), with decompression of nerve root(s), including partial facetectomy, foraminotomy and/or excision of herniated intervertebral disc; 1 interspace, cervical
63030	Laminotomy (hemilaminectomy), with decompression of nerve root(s), including partial facetectomy, foraminotomy and/or excision of herniated intervertebral disc; 1 interspace, lumbar
63035	Laminotomy (hemilaminectomy), with decompression of nerve root(s), including partial facetectomy, foraminotomy and/or excision of herniated intervertebral disc; each additional interspace, cervical or lumbar (List separately in addition to code for primary procedure)
63040	Laminotomy (hemilaminectomy), with decompression of nerve root(s), including partial facetectomy, foraminotomy and/or excision of herniated intervertebral disc, reexploration, single interspace; cervical
63042	Laminotomy (hemilaminectomy), with decompression of nerve root(s), including partial facetectomy, foraminotomy and/or excision of herniated intervertebral disc, reexploration, single interspace; lumbar

63045	Laminectomy, facetectomy and foraminotomy (unilateral or bilateral with decompression of spinal cord, cauda equina and/or nerve root[s], [e.g., spinal or lateral recess stenosis]), single vertebral segment; cervical
63047	Laminectomy, facetectomy and foraminotomy (unilateral or bilateral with decompression of spinal cord, cauda equina and/or nerve root[s], [e.g., spinal or lateral recess stenosis]), single vertebral segment; lumbar
63050	Laminoplasty, cervical, with decompression of the spinal cord, 2 or more vertebral segments;
63051	Laminoplasty, cervical, with decompression of the spinal cord, 2 or more vertebral segments; with reconstruction of the posterior bony elements (including the application of bridging bone graft and non-segmental fixation devices [e.g., wire, suture, mini-plates], when performed)
63056	Transpedicular approach with decompression of spinal cord, equina and/or nerve root(s) (e.g., herniated intervertebral disc), single segment; lumbar (including transfacet, or lateral extraforaminal approach) (e.g., far lateral herniated intervertebral disc)
63075	Discectomy, anterior, with decompression of spinal cord and/or nerve root(s), including osteophytectomy; cervical, single interspace
63081	Vertebral corpectomy (vertebral body resection), partial or complete, anterior approach with decompression of spinal cord and/or nerve root(s); cervical, single segment
63102	Vertebral corpectomy (vertebral body resection), partial or complete, lateral extracavitary approach with decom-pression of spinal cord and/or nerve root(s) (e.g., for tumor or retropulsed bone fragments); lumbar, single segment
63300	Vertebral corpectomy (vertebral body resection), partial or complete, for excision of intraspinal lesion, single segment; extradural, cervical
63304	Vertebral corpectomy (vertebral body resection), partial or complete, for excision of intraspinal lesion, single segment; intradural, cervical

HCPCS Codes

Code	Description
S2350	Diskectomy, anterior, with decompression of spinal cord and/or nerve root(s), including osteophytectomy; lumbar, single interspace

ICD10 Codes

Code	Description
C72.0	Malignant neoplasm of spinal cord
C79.40	Secondary malignant neoplasm of unspecified part of nervous system
G06.1	Intraspinal abscess and granuloma
D16.6	Benign neoplasm of vertebral column
D32.1	Benign neoplasm of spinal meninges
D33.4	Benign neoplasm of spinal cord
M40.35-M40.37	Flatback syndrome: thoracolumbar, lumbar or lumbosacral region (code range)
M41.05-M41.9	Scoliosis (code range: codes ending in 5 are thoracolumbar, ending in 6 are lumbar and ending in 7 are lumbosacral)
M43.00-M43.07	Spondylolysis: thoracolumbar, lumbar or lumbosacral region (code range)
M43.10-M43.19	Spondylolisthesis (code range)
M43.27	Fusion of spine, lumbosacral region
M48.00-M48.08	Spinal stenosis (code range)
M51.06	Intervertebral disc disorders with myelopathy, lumbar region
M51.16-M51.17	Intervertebral disc disorders with radiculopathy, lumbar/lumbosacral regions
M51.26-M51.27	Other intervertebral disc displacement, lumbar/lumbosacral regions
M51.36-M51.37	Other intervertebral disc degeneration, lumbar/lumbosacral regions
M51.46-M51.47	Schmorl's nodes, lumbar/lumbosacral regions
M51.86-M51.87	Other intervertebral disc disorders, lumbar/lumbosacral regions
M53.2X5-M53.2X7	Spinal instabilities: thoracolumbar, lumbar or lumbosacral region (code range)

Code	Description
M53.86-M53.87	Other specified dorsopathies, lumbar or lumbosacral region (code range)
M54.16-M54.17	Radiculopathy, lumbar/lumbosacral regions
M54.5	Low back pain
M79.604-M79.609	Pain in leg/limb (code range)
M79.651-M79.676	Pain in thigh/lower leg/foot/toes (code range)
M96.0	Pseudarthrosis after fusion or arthrodesis
M96.1	Postlaminectomy syndrome, not elsewhere classified
M99.23	Subluxation stenosis of neural canal of lumbar region
M99.33	Osseous stenosis of neural canal lumbar region
M99.43	Connective tissue stenosis of neural canal of lumbar region
M99.53	Intervertebral disc stenosis of neural canal of lumbar region
M99.63	Osseous and subluxation stenosis of intervertebral foramina of lumbar region
M99.73	Connective tissue and disc stenosis of intervertebral foramina of lumbar region
S32.000A-S32.059S	Fracture of lumbar spine (code range)

RESOURCE COORDINATION POLICY

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: STEREOTACTIC RADIOSURGERY (SRS) & STEREOTACTICBODY RADIATION THERAPY (SBRT)

POLICY EFFECTIVE DATE:	3/1/2025
Policy Control #:	1370/20.000434
Next Annual Review:	November, 2026

DISCLAIMER

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgement when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

PROCEDURE CODES

Stereotactic radiosurgery: 61796, 61797, 61798, 61799, 61800, 63620, 63621, 77371, 77372, 77432, C9795, G0339, G0340, G0563
Stereotactic body radiosurgery: 77373, 77435

DESCRIPTIONS

Stereotactic radiosurgery (SRS) is a technique that utilizes precisely targeted radiation to a tumor while minimizing radiation to adjacent normal tissue. It is used for the non-invasive destruction of intracranial lesions and some extracranial lesions that may be inaccessible or unsuitable for open surgery. In order to localize the treatment target and to achieve precise delivery of radiation, SRS relies on stereotactic guidance (using cerebral angiography, computerized tomography, and/or magnetic resonance imaging) and the use of a positioning frame to restrict head movement. Stereotactic body radiation therapy (SBRT) is used to treat extracranial sites as opposed to stereotactic radiosurgery which is used to treat intra-cranial and spinal targets.

Radiosurgery can be performed with:

- High energy X-rays produced by linear accelerators that are frame-based or robotically targeted (e.g., LINAC and CyberKnife®).
- Gamma rays (e.g., Gamma Knife®)

POLICY NAME: STEREOTACTIC RADIOSURGERY (SRS) & STEREOTACTICBODY RADIATION THERAPY (SBRT)

- With charged particle beams of protons, neutrons, or helium ions.

The three methods of radiation delivery differ technically in the source of radiation, size and shape of radiation field, and the range of radiation doses.

RELATED POLICIES/DOCUMENTS

Resource Coordination Policy:

- Proton Beam Therapy, 1370/20.000495

POSITION STATEMENT

CDPHP considers stereotactic radiosurgery (SRS) and stereotactic body radiation therapy (SBRT) medically necessary when performed in accordance with the Centers for Medicare and Medicaid coverage determination as outlined below:

Indications for SRS/SBRT (for Cranial and Spinal Lesions):

- Primary central nervous system malignancies, generally used as a boost or salvage therapy for lesions < 5 cm.
- Primary and secondary tumors involving the brain or spine parenchyma, meninges/dura, or immediately adjacent bony structures.
- Benign brain tumors and spinal tumors such as meningiomas, acoustic neuromas, other schwannomas, pituitary adenomas, pineocytomas, craniopharyngiomas, glomus tumors, hemangioblastomas.
- Cranial arteriovenous malformations, cavernous malformations, and hemangiomas
- Other cranial non-neoplastic conditions such as trigeminal neuralgia and select cases of medically refractory epilepsy. As a boost treatment for larger cranial or spinal lesions that have been treated initially with external beam radiation therapy or surgery (e.g., sarcomas, chondrosarcomas, chordomas, and nasopharyngeal or paranasal sinus malignancies).
- Metastatic brain or spine lesions, with stable systemic disease, Karnofsky Performance Status 40 or greater (or expected to return to 70 or greater with treatment), and otherwise reasonable survival expectations, OR an Eastern Cooperative Oncology Group (ECOG) Performance Status of 3 or less (or expected to return to 2 or less with treatment). Note that the higher a Karnofsky Performance Status is, the better a patient is doing. However, the lower an Eastern Cooperative Oncology Group (ECOG) Performance Status is, the better a patient is doing.
- Relapse in a previously irradiated cranial or spinal field where the additional stereotactic precision is required to avoid unacceptable vital tissue radiation.
- Choroidal and other ocular melanomas.

POLICY NAME: STEREOTACTIC RADIOSURGERY (SRS) & STEREOTACTICBODY RADIATION THERAPY (SBRT)

Indications for Stereotactic Body Radiation Therapy (SBRT):

- Primary tumors and tumors metastatic to the lung, liver, kidney, adrenal gland, or pancreas.
- Pelvic and head and neck tumors that have recurred after primary irradiation.
- For patients with clinically localized, low- to intermediate-risk prostate cancer.
- SBRT treatment, of anybody site or internal organ, is indicated for treatment of recurrence in or near previously irradiated regions when a high level of precision and accuracy or a high dose per fraction is indicated to minimize the risk of injury to surrounding normal tissues and treatment with conventional methods is not appropriate or safe for the particular patient (medical records must describe the specific circumstances, see documentation requirements below).

POLICY CONSIDERATIONS

A neuro-surgical consult is required prior to the initiation of stereotactic radiosurgery in an effort to provide the patient with all available treatment options related to their diagnosis.

SRS/SBRT procedures include the following components:

- Planning
- Position stabilization (attachment of a frame or frameless)
- Imaging for localization (CT, MRI, angiography, PET, etc.)
- Computer assisted tumor localization (i.e., "Image Guidance")
- Treatment planning – number of isocenters, number, placement and length of arcs or angles, number of beams, beam size and weight, etc.
- Isodose distributions, dosage prescription and calculation
- Setup and accuracy verification testing
- Simulation of prescribed arcs or fixed portals
- Radiation treatment delivery

SBRT is only indicated as primary treatment for tumor types or locations where the available published literature supports an outcome advantage over other conventional radiation modalities.

SBRT may be delivered in one to five sessions (fractions). Each fraction requires an identical degree of precision, localization, and image guidance.

SRS is typically performed in a single session, using a rigidly attached stereotactic guiding device, other immobilization technology and/or a stereotactic-guidance system.

The Karnofsky Performance Scale Index and Eastern Cooperative Oncology Group (ECOG) Performance Status allows patients to be classified as to their functional impairment, and is often used to compare effectiveness of different therapies and to assess the prognosis in individual patients.

POLICY NAME: STEREOTACTIC RADIOSURGERY (SRS) & STEREOTACTICBODY RADIATION THERAPY (SBRT)

- Karnofsky Performance Scale Index
- ECOG Performance Status

EXCLUSIONS

SRS/SBRT (for Cranial and Spinal Lesions)
SRS is not considered medically necessary under the following circumstances:

- Treatment for anything other than a severe symptom or serious threat to life or critical functions.
- Treatment unlikely to result in functional improvement or clinically meaningful disease stabilization, not otherwise achievable.
- Patients with wide-spread cerebral or extra-cranial metastases with limited life expectancy unlikely to gain clinical benefit within their remaining life.
- Patients with poor performance status (Karnofsky Performance Status less than 40 or an ECOG Performance greater than 3). Note that the higher a Karnofsky Performance Status is, the better a patient is doing. However, the lower an Eastern Cooperative Oncology Group (ECOG) Performance Status is, the better a patient is doing.
- Cobalt-60 pallidotomy is non-covered.

Stereotactic Body Radiation Therapy (SBRT):
SBRT is not considered medically necessary under the following circumstances for any condition:

- Treatment is unlikely to result in clinical cancer control and/or functional improvement.
- The tumor burden cannot be completely targeted with acceptable risk to critical normal structures.
- The patient has a poor performance status (Karnofsky Performance Status less than 40 or Eastern Cooperative Oncology Group (ECOG) Status of 3 or worse). Note that the higher a Karnofsky Performance Status is, the better a patient is doing. However, the lower an Eastern Cooperative Oncology Group (ECOG) Performance Status is, the better a patient is doing.
- Recurrent (other than pelvic and head and neck tumors) or metastatic disease could be treated by conventional methods (record must describe why other radiation therapy measures are not appropriate or safe for the particular patient).
- Since the goal of SBRT is to maximize the potency of the radiotherapy by completing an entire course of treatment within an extremely accelerated time frame, any course of radiation treatment extending beyond five fractions is not considered SBRT. SBRT is meant to represent a complete course of treatment and not to be used as a boost following a conventionally fractionated course of treatment.
- Primary treatment of lesions of bone, breast, uterus, ovary, and other internal organs not listed earlier in this policy as covered is not considered medically necessary.

MEDICAL POLICY

Medical Policy Title	**Surgical Management of Sleep Disorders**
Policy Number	**7.01.41**
Current Effective Date	**January 1, 2027**
Next Review Date	**January 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Nasal Surgery

A. Nasal surgery is **medically appropriate** to correct a nasal obstruction that prohibits the use of continuous positive airway pressure (CPAP) device and bilevel positive airway pressure (BiPAP).

B. Septoplasty, turbinate reduction, and polypectomy are **not medically necessary** for obstructive sleep apnea (OSA).

II. Surgical Bypass of the Airway Tracheostomy

A. Tracheostomy is **medically appropriate** for the treatment of severe, life threatening OSA.

III. Upper Airway Surgery

A. Palatopharyngoplasty (e.g., Uvulopalatopharyngoplasty (UPPP), Uvulopharyngoplasty) **AND** Hyoid Suspensions for the treatment of OSA are **medically appropriate** when the following criteria are met:

1. Documented OSA with an apnea-hypopnea index (AHI) or respiratory disturbance index (RDI) of 15 or greater events per hour, regardless of symptoms; **or**
2. Documented OSA with an AHI or RDI of five (5) to 14 events per hour, accompanied by symptoms of excessive daytime sleepiness, impaired cognition, mood disorders, insomnia, or documented cardiovascular diseases, including hypertension and ischemic heart disease; **and**
3. Failure of all forms of medical management of OSA, including documented intolerance to positive airway pressure (e.g., CPAP, BiPAP) or intolerance.

B. Tonsillectomy and Adenoidectomy:

1. Tonsillectomy and adenoidectomy are **medically appropriate** for the following indications:
   a. treatment of OSA; **or**
   b. to correct an upper airway obstruction that prohibits the use of CPAP/BiPAP.

C. Radiofrequency Ablation or Somnoplasty of Palatal Tissues is **not medically necessary** for the treatment of OSA.

D. Laser-assisted Uvulopalatoplasty (LAUP) is **not medically necessary** for the treatment of OSA.

E. Expansion Sphincter Pharyngoplasty/Expansion Sphincteroplasty (ESP) is **investigational.**

F. Injection Snoreplasty:

1. Injection Snoreplasty is **not medically necessary** for the treatment of snoring alone.
2. Injection Snoreplasty is **investigational** for the treatment of OSA.

G. Cautery-Assisted Palatal Stiffening Operation (CAPSO):

1. CAPSO is **not medically necessary** for snoring alone.
2. CAPSO is **investigational** for the treatment of OSA.

H. Palatal Implant System (e.g., Pillar Palatal Implant):

1. Palatal Implant Systems are **not medically necessary** for snoring alone.
2. Palatal Implant Systems are **investigational** for the treatment of OSA.

IV. Lower Airway Surgery

A. Jaw Realignment Surgery (e.g., inferior sagittal mandibular osteotomy, genioglossal advancement, hyoid myotomy and suspension, maxillomandibular osteotomy and advancement)*:*

1. Jaw realignment surgery is **medically appropriate** for the treatment of OSA in individuals who meet the criteria for UPPP, as stated in Policy Statement III.A.

B. Radiofrequency Ablation or Somnoplasty of the Base of the Tongue is **not medically necessary** for the treatment of OSA.

C. Tongue Suspension Suture Systems (e.g., AIRvance [formerly known as the Repose System], Encore System) are **investigational** for the treatment of OSA.

V. Hypoglossal Nerve/Upper Airway Stimulation

A. The approved United States Food and Drug Administration (FDA) hypoglossal nerve upper airway stimulation (e.g**.**, Inspire II Upper Airway Stimulation system, Inspire 3028 System for Upper Airway Stimulation (UAS) Therapy) device is **medically appropriate** for the treatment of moderate-to-severe OSA, when **ALL** the following criteria are met for each listed age group:

1. Adult ($\geq$ 18 years):

a. AHI $\geq$ 15 and $\leq$ 100;

b. $\leq$ 25% central apneas and mixed apneas (e.g., AHI and apneas confirmed with a in facility or attended polysomnography);

c. documentation of failure or inability to use or tolerate CPAP (e.g., residual AHI ≥ 15 or failure to use CPAP ≥ 4 hours per night for ≥ 5 nights per week);

d. documentation of all previous treatment measures and why they have been unsuccessful;

e. absence of complete concentric collapse of the soft palate; **and**

f. Body Mass Index (BMI) < 40km/m2;

2. Adolescents or young adults (aged 13 to 18 years) with Down Syndrome:

a. AHI > 10 and less than ≤ 50;

b. ≤ 25% central or mixed apneas;

c. are either contraindicated for adenotonsillectomy or do not respond effectively to the procedure;

d. do not have complete concentric collapse at the soft palate level on drug induced sleep endoscopy;

e. Body Mass Index ≤ 95th percentile for age;

f. have either a tracheotomy or have been confirmed to fail, or cannot tolerate, PAP therapy despite attempts to improve compliance; **and**

g. have followed standard of care in considering all other alternative/adjunct therapies.

B. Upper airway stimulation therapy is **contraindicated** when the individual:

a. has any condition or procedure that would affect neurological control of the upper airway;

b. is unable or does not have the necessary assistance to operate the sleep remote;

c. is pregnant or plans to become pregnant;

d. has an implantable device that may have unintended interactions with the upper airway stimulation system (e.g., Inspire system).

C. Hypoglossal nerve/upper airway treatment of OSA that does not meet the above listed criteria in PS V.A. or B. is considered **investigational**.

VI. Surgical treatment for snoring without polysomnographic evidence of OSA is considered **not medically necessary**.

VII. Cardiac pacing or atrial overdrive pacing is **investigational** for the treatment of OSA.

VIII. Device Repair

A. Repair of a medically necessary device or components not under warranty will be considered **medically appropriate** when the following criteria are met:

1. Physician documentation includes **ALL** the following:

a. date of device implantation/initiation;

b. manufacturer warranty information, if applicable;

c. attestation that the individual has been compliant with the use of device and will continue to benefit from the use of device;

2. The device is no longer functioning adequately; and **BOTH** of the following criteria are met:

a. inadequate function interferes with activities of daily living; **and**

b. repair is expected to make the equipment fully functional (as defined by manufacturer).

B. Repair of equipment damaged due to the individual neglect, theft, abuse, or when another available coverage source is an option (e.g., homeowners, rental, auto, liability insurance, etc.) is **ineligible for coverage.**

11.01.03 Experimental or Investigational Services

POLICY GUIDELINE(S)

I. Surgery is not the first treatment of choice for OSA. It is reserved for individuals who have failed all forms of medical management of OSA, or are intolerant of CPAP, BiPAP, or oral appliances.

II. In severe OSA disease, surgery may not be curative, and follow-up studies may be warranted post-operatively.

III. For those individuals who have been found to have multiple levels or anatomical sites (e.g., hypopharyngeal, retropalatal, and/or retro lingual) of OSA on clinical evaluation, a simultaneous combination of surgical procedures may be appropriate for the best surgical outcome and to minimize operative risk. Nasal surgery is not considered part of a multi-level surgery to correct OSA. If a nasal obstruction precludes the use of CPAP, then nasal surgery to allow the use of CPAP should be performed first.

DESCRIPTION

Obstructive sleep apnea (OSA) is the cessation of airflow through the nose and mouth for at least 10 seconds with a respiratory effort noted and is usually associated with a reduction in blood oxygen

saturation. Features of OSA include daytime somnolence, disordered sleep, and a variety of clinical symptoms. It is also common to find decreased motor and perceptual skills while awake, which correlates with the severity of hypoxia during sleep. The syndrome is most common in middle-aged, obese, male smokers.

In individuals with OSA, the normal pharyngeal narrowing is accentuated by anatomic factors, such as a short neck, elongated palate and uvula, or large tonsillar pillars with redundant lateral pharyngeal wall mucosa. OSA may also be associated with a wide variety of craniofacial abnormalities, including micrognathia, retrognathia or maxillary hypoplasia.

When anatomical obstructions exist, surgical interventions are used. Obstruction can occur at several different locations along the airway, and in specific circumstances, combined surgical procedures can offer a higher overall success rate than one single procedure alone. Due to the complexity of airway narrowing or collapse during sleep, one surgical procedure may not eradicate the person's sleep apnea. Procedures such as septoplasty, nasal turbinectomies or nasal polypectomies may be indicated for correction of nasal airway obstruction, their role in treating multi-level OSA is very limited.

When individuals with OSA are not able achieve benefit with non-invasive positive pressure therapy (PAP) or fail the gold standard of treatment in the form of CPAP, a second-line treatment may be a surgical option.

The goal of surgery is to enlarge the airway and prevent airway collapse and oxygen desaturation, to prevent the clinical symptoms of OSA: excessive daytime sleepiness, impaired cognition, and mood disorders. Surgery is site-specific, performed to enlarge a certain portion of the airway.

Types of Nasal Surgery

- Septoplasty corrects a deviated septum, which may obstruct the nasal airway.
- Turbinate reduction reduces the size of one of the three turbinate in each nostril, which can improve the size of the nasal airway. The surgery may be performed with lasers, cautery, or radiofrequency ablation.
- Polypectomy removes nasal polyps that obstruct the nasal airways.

Upper Airway Surgery

- Uvulopalatopharyngoplasty (UPPP) involves the removal of the uvula and trimming of the lower edge of the soft palate. The surgery may include several technical variations. All techniques include the basic UPPP procedure, but often additional surgery is performed, such as tonsillectomy. UPPP with inferior sagittal osteotomy with hyoid suspension is one variation proposed to improve the surgical outcome.
- Radio-frequency ablation of soft palate tissue, or somnoplasty system, uses a device consisting of an electrosurgical (RF) generator and tissue-coagulating electrodes that ablate soft tissues in the palate or uvula.
- Laser-assisted uvulopalatoplasty (LAUP) involves the progressive removal of the back edge of the palate and reduction in the size of the uvula. It is most frequently performed with a carbon

dioxide laser and is typically performed over several surgical sessions in an outpatient setting.

- Expansion sphincter pharyngoplasty/expansion sphincteroplasty (ESP) is a modification of a UPPP in which the lateral pharyngeal wall is stiffened to prevent collapse. ESP consists of a tonsillectomy, expansion pharyngoplasty, rotation of the palatopharyngeal muscle, partial uvulectomy, and closure of the anterior and posterior tonsillar pillars.
- Tonsillectomy and adenoidectomy are, respectively, procedures to remove enlarged tonsils, which may narrow the width of the upper airway, and the adenoids, which are at the back of the nose and may obstruct the nasal airway. Removal of tonsils and adenoids is performed most often in children with sleep apnea. Adenoids usually shrink with age and only rarely require removal in adults.
- Injection snoreplasty involves the injection of a sclerosing agent (tetradecyl sulfate/Sotradecol) into the soft palate, which causes scarring and subsequent stiffening of the soft palate. This is thought to reduce the flutter of the soft palate, which is the cause of primary snoring.
- Cautery-assisted palatal stiffening operation (CAPSO) is a procedure in which electrocautery is utilized to remove a portion of the soft palate and uvula. It is carried out under local anesthesia, on an outpatient basis.
- Palatal implant system involves insertion of three narrow bands of braided polyester under the skin of the soft palate using a delivery tool. The implant has been proposed for the treatment of snoring and for the treatment of palate-related mild to moderate sleep apnea. Once in place, the implant stiffens the palate by mechanical means and induces a fibrotic response that incapsulates and secures the implants, further stiffening the palatal tissue. Palatal implants, though designed to be permanent, are removable. Implantation is carried out under local anesthesia.

<u>Lower Airway Surgery</u>

- Jaw realignment surgery (e.g., inferior sagittal mandibular osteotomy, genioglossal advancement, hyoid myotomy and suspension, maxillomandibular osteotomy and advancement) is a more aggressive surgical procedure than UPPP. It has been used to relieve obstruction in OSA individuals who meet the criteria for UPPP.
- A tongue suspension suture system (e.g., Airvance, Medtronic, Inc) involves preventing the tongue from falling back during sleep. The Airvance System uses a titanium screw in the chin, which is attached to a permanent stitch through the tongue to pull it forward. The Encore System is similar to the Airvance System but creates a suture loop within the tongue without having to create penetrations through the mucosal surface of the tongue.
- Radiofrequency ablation, or Somnoplasty System, uses a device consisting of an electrosurgical (RF) generator and tissue-coagulating electrodes that ablate soft tissues, creating volumetric tissue reduction of the tongue.

<u>Surgical Bypass of the Airway</u>

- A tracheostomy bypasses the narrow segments of the airway that cause obstruction and creates

an opening in the neck that allows the individual to breathe unobstructed at night. This is done in severe, life-threatening cases of sleep apnea.

Hypoglossal Nerve/Upper Airway Stimulation

- Electrical stimulation of the hypoglossal nerve has been proposed as a method of maintaining upper airway patency by augmenting tone to the upper airway. The implant device, which consists of a pulse generator, a stimulation lead, and a sensing lead, is designed to detect the respiratory effort and maintain airway patency with mild stimulation of the hypoglossal nerve. Therapy settings are stored in the pulse generator and configured by the physician using an external programmer. The individual uses a remote to start therapy before going to sleep and to stop therapy when awakened. The sleep remote also provides the ability to pause therapy and to adjust stimulation amplitude within physician-defined limits.

Atrial Overdrive Pacing

- It has been found that bradycardia frequently occurs during episodes of apnea. Therefore, atrial overdrive pacing after implantation of a pacemaker has been proposed as a treatment to reduce the incidence of obstructive sleep apnea events.

SUPPORTIVE LITERATURE

Candidates for surgical options require appropriate selection. Factors to consider are the polysomnographic report, age, BMI, and objective upper airway evaluation measures.

Kent et al (2021) conducted a systematic review and meta-analysis to support the development of the American Academy of Sleep Medicine clinical practice guidelines on when to refer adults with OSA for surgical consultation. Findings show that surgical therapy (upper airway or bariatric surgery) is associated with clinically significant improvements in excessive daytime sleepiness, snoring, AHI, RDI, ODI, blood pressure and quality of sleep. The AASM guideline recommendations are based on a systematic review and meta-analysis of 274 studies of surgical interventions, including procedures such as Uvulopalatopharyngoplasty (UPPP), modified UPPP, MMA, tongue base suspension, and hypoglossal nerve stimulation (Kent et al 2021). The systematic review deemed most studies included data of low quality, consisting of mostly observational data.

LAUP studies have shown that a large proportion of patients post-operatively developed significant worsening of objective sleep parameters. Camacho et al (2017) conducted a systematic review and meta-analysis on the effectiveness and the outcomes of LAUP as a treatment for OSA. The review evaluated pre-and-post-operative outcomes such as AHI, oxygen saturation levels, and quality of life measurements. Twenty-three adult studies (717 patients) reported outcomes. LAUP reduced AHI by 32% among all participants. Individual participant data analyses demonstrated a 23% success rate (≥ 50% reduction in AHI and < 20 events/hour) and an 8% cure rate. A total of 44% of patients had worsening of their AHI after LAUP. Lowest oxygen saturation (LSAT) improved minimally. Recommendations suggest that LAUP should be performed with caution or not perform at all given the unfavorable results of study.

Snoreplasty and CAPSO are intended treatment therapies for snoring, and not for the treatment of OSA (Lee et al 2014). Most published studies on this treatment have been non-randomized,

observational studies with highly selected enrolled participants. These studies also fail to report long-term outcomes or recurrence rates.

The Pillar Palatal Implant received FDA approval for the treatment of snoring in 2003 and as a treatment for OSA in September 2004. There is insufficient peer-reviewed evidence to support the use of the Pillar implant as a treatment for OSA. The literature consists of small case series investigating its use for snoring. Studies with OSA patients had very small sample sizes and limited follow-up, and were vendor sponsored (Nordgard et al (2006); Friedman et al (2006)).

Many individuals with OSA also suffer from nocturnal bradycardia or tachyarrhythmias. It has been observed that, in some patients, the use of a pacemaker to increase the heart rate and cardiac function during sleep could also reduce the incidence of apneic episodes. Although a clinical study by Garrigue et al (2002) found that atrial overdrive pacing significantly reduced the number of episodes of central and obstructive sleep apnea, but these positive findings have not been validated in any of the newer, well-designed studies. Atrial overdrive pacing has not been found to reduce the number of apnea and/or hypopnea events in patients with OSA (Krahn et al (2006); Unterberg et al (2005); Luthje et al (2005); Simantirakis et al (2005); Pepin et al (2005)).

Upper airway stimulation (UAS) leads to significant reductions in the AHI, the ODI, and the ESS in older patients, despite higher age with multiple co-morbidities. Advanced age was not a limiting factor for surgical procedure or treatment outcomes. The main result of this study is a significant reduction of the AHI in younger and older subjects: 84% decrease in younger subjects and 80.8% decrease in older subjects where the AHI declined below a level of 15 events per hour (the generally accepted values that define mild sleep apnea). Furthermore, the level of daytime sleepiness also declined in 69.6% of younger and in 72% of older subjects where the value of ESS was below 10 points. (Zhu et al 2018).

The largest cohort study done to date, which focused exclusively on UAS therapy outcomes, consisted of a study of 47 patients, 30 of whom had undergone a previous surgery and 16 of whom had not suffered from moderate-to-severe OSA, but were surgical candidates for Hypoglossal Nerve Stimulation (HNS_ therapy). The study examined AHI and nadir oxyhemoglobin saturation (NOS) as measured by polysomnography; secondary measures included ESS. The study revealed an overall reduction in AHI by 90%, which translated to a success rate of 96% and cure rate of 81%. (Mahmoud et al 2018).

Patients with moderate-to-severe OSA and an inability to adhere to positive pressure therapy, who underwent HGNS, were compared to a historical cohort of patients who were intolerant of CPAP who underwent UPPP. Data included BMI, as well as pre- and post-implant AHI. UAS resulted in an approximately 90% reduction in AHI, while traditional airway surgery resulted in an approximately 30% reduction in AHI. In addition, 65% of the patients in the UAS cohort demonstrated a reduction in AHI from the moderate-to-severe range into the normal range (AHI < 5), compared to only 20% of the patients in the UPPP group. (Shah et al 2018).

Liu et al (2022) published a systematic review investigating HNS in adolescents with Down Syndrome and OSA. A total of nine studies were included with a follow up period ranging from two to 58 months; six studies had sample sizes fewer than ten patients. The largest of the included studies was

a prospective cohort study published by Yu et al (2022), which is summarized below. In an analysis that included 104 patients, AHI scores were significantly reduced in patients after HNS (mean AHI reduction, 17.43 events/h; 95% CI, 13.98 to 20.88events/h; p<.001). Similarly, in an analysis that included 88 patients, OSA-18 survey scores were significantly reduced after HNS (mean OSA-18 reduction, 1.67; 95% CI, 1.27 to 2.08; p<.001).

Yu et al (2022) reported on the safety and effectiveness of HNS in 42 adolescents with Down Syndrome and severe OSA (AHI of 10 events/h or greater). This was a single-group, multicenter, cohort study with a 1-year follow-up that included non-obese (BMI < 95%) children and adolescents aged 10 to 21 years who were refractory to adenotonsillectomy and unable to tolerate CPAP. Patients who were included had an AHI between 10 and 50 on baseline polysomnography (PSG); the mean baseline AHI was 23.5 (SD, 9.7). All patients included tolerated HNS without any intraoperative complications. The most common complication was tongue or oral discomfort or pain, which occurred in 5 (11.9%) patients and was temporary, lasting weeks or rarely, months. Four patients (9.5%) had device extrusion resulting in readmissions to replace the extruded device. At 12 months, there was a mean decrease in AHI of 12.9 (SD, 13.2) events per hour (95% CI, -17.0 to -8.7 events/h). At the 12-month PSG, 30 of 41 patients (73.2%) had an AHI of less than 10 events/h, 14/41 patients (34.1%) had an AHI of less than 5 events/h, and 3/41 patients (7.3%) had an AHI of less than 2 events/h. There was also a significant improvement in quality-of-life outcomes. The mean improvement in the OSA-18 total score was 34.8 (SD, 20.3;95% CI, -42.1 to -27.5) and the ESS improved by 5.1 (SD, 6.9; 95% CI, -7.4 to -2.8).

Alrubasy et al (2024) evaluated the efficacy of Apnex, Inspire, and ImThera HNS devices in changing the severity of OSA in adults (> 18). The efficacy of each device was assessed individually, and the reported outcomes were analyzed at short-term (≤ 1 year) and long term (> 1 year) intervals. Data was based on a total of 549 middle aged (55 ± 9.2) overweight (BMI=29 ± 3.9) individuals. The Inspire device significantly reduced the AHI by -20.14 events/hour (h) in the short term and -15.91 events/h in the long term. ODI decreased by -14.16 events/h (short term) and -12.95 events/h (long term). Patient-reported outcomes showed decreased ESS scores by -5.02 (short term) and -4.90 (long term) and FOSQ scores by 3.58 (short term) and 3.28 (long term). The Apnex device and the ImThera devices featured similar improvements but to a lesser extent. No significant differences in efficacy were observed among the three devices. Study findings were consistent with previous meta-analyses examining the effects of HNS on OSA.

Kim et al (2023) compared HNS to other OSA treatments in a systematic review and meta-analysis. Studies included measured polysomnography parameters and assessed sleep apnea-related quality of life (Epworth Sleepiness Scale (ESS)) both before and after HNS, and compared these outcomes with control, CPAP, or airway surgery (uvulopalatopharyngoplasty, expansion sphincter pharyngoplasty, or tongue base surgery) groups. A total of 10 studies with 2209 patients (mean BMI ≤ 30 kg/m2 in every study) who were treated with HNS or alternative interventions. HNS improved post-treatment AHI < 10 and < 15 events/hour compared with other surgical options including uvulopalatopharyngoplasty, expansion sphincterpharyngoplasty, or tongue-based surgery (odds ratio [OR]; 5.33;95% CI, 1.21 to 23.42).

ImThera Medical Targeted Hypoglossal Neurostimulation Study #3 (THN3) investigated the efficacy

and safety of targeted HNS of the proximal hypoglossal nerve in individuals with moderate-to-severe OSA (AHI 20-60 events per hour) and a BMI of 35 kg/m2 or less (Schwartz et al. 2023). This was a multicenter, randomized trial where all individuals (N=138) were implanted with the HNS system (aura6000; ImThera Medical) and randomly assigned 2:1 to HNS device activation at one or four months after implant for the treatment and control groups, respectively. Efficacy was measured at month four, and after 11 months of therapy (study months 12 and 15 for treatment and control groups, respectively). The study included mostly males (86.2%) and Caucasian individuals (91.3%). The results demonstrated that at month four, the treatment group had significantly better outcomes compared to the control group for AHI and oxygen desaturation index (ODI) scores. After 11 months of active therapy, the difference between the treatment and control groups was not statistically significant for AHI (RR, -7.5; 95% CI, -16 to 1.4) but remained significant for ODI (RR, 10.4; 95% CI, 1.6 to 18.8). The authors noted that the results should only be applied to individuals with moderate to severe OSA and a BMI of 35 kg/m2 or less.

Woodson et al (2024) published the DREAM study, which aimed to evaluate the safety and efficacy of a novel bilateral hypoglossal nerve stimulation device (HNSBL), the Genio device. Adult patients with moderate-to-severe obstructive sleep apnea who refused, failed, or did not tolerate positive airway pressure therapy underwent implantation and nightly use of the Genio system. The Genio system was implanted in 113 participants. Eleven serious adverse events occurred in ten (8.7%) participants. AHI and oxygen desaturation index responses were achieved in 63.5% (73/115, P = .002) and 71.3% (82/115, P < .001), respectively. Secondary endpoint analysis revealed significant changes in mean AHI (218.3 ± 11.8 events/h, P < .001), oxygen desaturation index (217.7 ± 14.6 events/h, P < .001), and sleep time with blood oxygen saturation less than 90% (6.9 ± 10.7%, P < .001). The study design had several limitations including a small sample size, homogeneous study sample, industry sponsorship and lack of follow up or study completion by 27 participants.

PROFESSIONAL GUIDELINE(S)

National Institute for Health and Care Excellence 2017 recommendation states that HNS for moderate to severe obstructive sleep apnea should only be used with special arrangements for clinical governance, in clinical trials, stating the evidence on the safety and efficacy of the HNS is limited in quantity and quality.

The AASM (2021) strongly recommends that clinicians discuss a referral to a sleep surgeon with adults with OSA and body mass index (BMI) < 40 kg/m2 who are intolerant or unaccepting of PAP. The AASM makes a conditional recommendation that clinicians discuss referral to a sleep surgeon with adults with OSA, BMI < 40 kg/m2, and persistent inadequate PAP adherence due to pressure-related side effects. The available data (very low-quality), suggests that upper airway surgery has a moderate effect in reducing minimum therapeutic PAP level and increasing PAP adherence. In adults with OSA and obesity (class II/III, BMI > 35) who are intolerant or unaccepting of PAP, the AASM strongly recommends discussion of referral to a bariatric surgeon, along with other weight-loss strategies.

The American Academy of Otolaryngology - Head and Neck Surgery (AAO-HNS; 2021) position statement supports surgical management of OSA when part of a comprehensive approach in the

medical and surgical management of adults with OSA. Approved treatments include:

- Tracheostomy
- Nasal and pharyngeal airway surgery
- Tonsillectomy and adenoidectomy
- Palatal advancement
- UPPP
- Genioglossal advancement
- Hyoid myotomy
- Midline glossectomy
- Tongue suspension
- Maxillary and mandibular advancement
- Hypoglossal nerve stimulation as an effective second-line treatment of moderate-to-severe OSA.

According to the 2021 American Academy of Sleep Medicine (AASM) clinical practice guidelines, PAP therapy is strongly recommended as the first-line treatment for adults with OSA, especially those experiencing excessive daytime sleepiness. The guidelines support initiating PAP therapy using either auto-adjusting PAP (APAP) at home or in laboratory titration and recommend ongoing treatment with CPAP or APAP. The guidelines highlight that the clinical effectiveness of PAP therapy may be limited for individuals who struggle with adherence or do not experience sufficient therapeutic benefit. In such situations, alternative treatment options including surgical interventions may be more suitable, depending on the individual's specific circumstances and needs.

The AASM holds the position that while home sleep apnea testing (HSAT) is appropriate for diagnosing OSA in select adult populations, in laboratory PSG remains the preferred standard for more complex clinical scenarios, particularly when:

- Precise measurement of the Apnea-Hypopnea Index (AHI) is required;
- Exclusion of central sleep apnea is clinically important; or
- When advanced therapies such as HNS (e.g., Inspire therapy) are being considered.

REGULATORY STATUS

The United States Food and Drug Administration (FDA) regulates sleep devices and appliances as medical devices. All sleep devices and appliances including related components require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2025 Dec 11]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most serious type of recalls. Available from: Medical Device Recalls | FDA [accessed 2025 Dec 11]

On April 30, 2014, the FDA granted pre-market approval for the Inspire Upper Airway Stimulation (UAS) system (Inspire Medical Systems) for use in treating a subset of individuals, aged 22 years and older, with moderate-to-severe obstructive sleep apnea (AHI of 20 to 65) who have failed or could not tolerate CPAP treatments, who do not have complete concentric collapse at the level of the soft palate and a body mass index (BMI) less than 32.

In June 2023, the FDA expanded indications for Inspire UAS system. The update increased the upper limit of the AHI to 100 events per hour from 65 and raised the BMI warning from 32 to 40. The FDA lowered the age to 18 years old for individuals with moderate to severe OSA. The FDA added indications for pediatric individuals aged 13-18 years old with Down Syndrome and who have an AHI greater than 10 and less than 50. Inspire Medical Systems, Inc. [Internet] [accessed 2025 Dec 11] Available from: https://www.accessdata.fda.gov/cdrh_docs/pdf13/P130008S090A.pdf

On August 8, 2025, the FDA granted premarket approval for the Genio system for a subset of patients who meet specific criteria.

The FDA defines positive airway pressure (PAP) failure as an inability to eliminate OSA (AHI of greater than 15 despite PAP usage), and PAP intolerance is defined as:

1. Inability to use PAP (greater than five (5) nights per week of usage; usage defined as greater than four (4) hours of use per night); or
2. Unwillingness to use PAP (for example, an individual returns the PAP system after attempting to use it).

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
21141-21155, 21193-21206, 21244	Jaw realignment surgery (code ranges)
30520	Septoplasty or submucous resection, with or without cartilage scoring, contouring or replacement with graft
30620	Septal or other intranasal dermatoplasty (does not include obtaining graft)
31600	Tracheostomy, planned (separate procedure)

Code	Description
41512 (E/I)	Tongue base suspension, permanent suture technique
41530 (NMN)	Submucosal ablation of the tongue base, radiofrequency, one or more sites, per session
42145	Palatopharyngoplasty (e.g., uvulopalatopharyngoplasty, uvulopharyngoplasty)
42820	Tonsillectomy and adenoidectomy; younger than age 12
42821	Tonsillectomy and adenoidectomy; age 12 or over
64568	Open implantation cranial nerve (e.g., vagus nerve) neurostimulator electrode array and pulse generator
64582	Open implantation of hypoglossal nerve neurostimulator array, pulse generator, and distal respiratory sensor electrode or electrode array
64583	Revision or replacement of hypoglossal nerve neurostimulator array and distal respiratory sensor electrode or electrode array, including connection to existing pulse generator
64584	Removal of hypoglossal nerve neurostimulator array, pulse generator, and distal respiratory sensor electrode or electrode array
95970	Electronic analysis of implanted neurostimulator pulse generator/transmitter (e.g., contact group[s], interleaving, amplitude, pulse width, frequency [Hz], on/off cycling, burst, magnet mode, dose lockout, patient selectable parameters, responsive neurostimulation, detection algorithms, closed loop parameters, and passive parameters) by physician or other qualified health care professional; with brain, cranial nerve, spinal cord, peripheral nerve, or sacral nerve, neurostimulator pulse generator/transmitter, without programming
95976	Electronic analysis of implanted neurostimulator pulse generator/transmitter (e.g., contact group[s], interleaving, amplitude, pulse width, frequency [Hz], on/off cycling, burst, magnet mode, dose lockout, patient selectable parameters, responsive neurostimulation, detection algorithms, closed loop parameters, and passive parameters) by physician or other qualified health care professional; with simple cranial nerve neurostimulator pulse generator/transmitter programming by physician or other qualified health care professional
95977	Electronic analysis of implanted neurostimulator pulse generator/transmitter (e.g., contact group[s], interleaving, amplitude, pulse width, frequency [Hz], on/off cycling, burst, magnet mode, dose lockout, patient selectable parameters, responsive neurostimulation, detection algorithms, closed loop parameters, and passive parameters) by physician or other qualified health care professional; with complex cranial nerve neurostimulator pulse generator/transmitter programming by

CENTERS FOR MEDICARE AND MEDICAID SERVICES (CMS)

Surgical management of obstructive sleep apnea is not addressed in National or Regional Medicare coverage determinations or policies.

PRODUCT DISCLAIMER

- Services are contract dependent; if a product does not cover a service, medical policy criteria do not apply.
- If a commercial product (including an Essential Plan or Child Health Plus product) covers a specific service, medical policy criteria apply to the benefit.
- If a Medicaid product covers a specific service, and there are no New York State Medicaid guidelines (eMedNY) criteria, medical policy criteria apply to the benefit.
- If a Medicare product covers a specific service, and there is no national or local Medicare coverage decision for the service, medical policy criteria apply to the benefit.

Disclaimer Notice

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgment when deciding the most appropriate care to enrollees. The CDPHP coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

Background

Castleman disease is a rare blood disease defined by enlarged lymph nodes with a particular appearance when reviewed under the microscope and a broad range of symptoms and laboratory findings. Castleman disease is first classified based on the number of regions of enlarged lymph nodes that have these abnormal features. Unicentric Castleman disease (UCD) involves a single region of enlarged lymph nodes whereas multicentric Castleman disease (MCD) involves multiple regions of enlarged lymph nodes and body-wide inflammation. People with MCD often develop drenching night sweats, fatigue, unexplained weight loss, rash, fevers, shortness of breath, or swelling. The inflammation can take the form of blood count abnormalities, fluid accumulation in the legs, lungs, or abdomen, rash, kidney failure, or other blood test abnormalities.

A 2014 study estimated an incidence of 6500-7700 cases/year of CD in the United States, with approximately 75% estimated to have unicentric disease and the remaining 25% to be split between HHV-8-associated MCD or HHV-8-negative/iMCD. However, more recent data from a 2022 study estimated that 40% of incident cases are UCD and 50% are idiopathic MCD (iMCD). The prevalence of iMCD is estimated at 6.9-9.7 cases per million in the US.

Although all subtypes of Castleman disease have had reports of cases with elevated levels of interleukin 6 (IL-6), IL-6 is not elevated or the pathologic driver in all cases. However, IL-6 does appear to drive symptomatology in idiopathic (non-HHV-8) MCD (iMCD), with anti-IL-6 therapy showing effective symptom reduction and lymph node shrinking in some patients.

Sylvant (siltuximab) is an IL-6 antagonist and is the only FDA-approved agent for treatment of iMCD. For patients with severe disease manifestations, chemotherapy and high-dose corticosteroids are recommended if the patient's disease progresses while on siltuxumab. Approximately half of iMCD patients do not improve with anti-IL-6 therapy. For these patients, there is no consensus standard of treatment though rituximab, sirolimus, ruxolitinib, adalimumab, and a combination of thalidomide/cyclophosphamide/dexamethasone have all been used.

Summary

Effective Date of Policy:	2/12/2026
Indications	Treatment of patients with multicentric Castleman's disease (MCD) who are human immunodeficiency virus (HIV) negative and human herpesvirus-8 (HHV-8) negative
ICD10 Diagnosis Codes	D47.Z2
HCPCS Code	J2860
Availability	Single dose vial of 100 mg or 400 mg lyophilized powder
Duration	Initial: 1 year Continuation: 1 year

Required Criteria for Initial Approval

All of the following conditions for the requested indication must be met in order to approve therapy

Indication	Inclusion Criteria	Dosing Regimen
Indication Treatment of patients with multicentric Castleman's disease (MCD) who are human immunodeficiency virus (HIV) negative and human herpesvirus-8 (HHV-8) negative ICD10: D47.Z2	• Must be prescribed by an oncologist or hematologist • Must have a diagnosis of Multicentric Castleman's disease (MCD) with pathological confirmation on biopsy of involved tissue AND • Must be human immunodeficiency virus (HIV) negative and human herpesvirus-8 (HHV-8) negative	• 11 mg/kg given over 1 hour by intravenous infusion every 3 weeks

Continuation Criteria

- Recertification will be for 1 year
- Further approval will require submission of documentation supporting the absence of disease progression (defined as increase in symptoms, radiologic progression, or deterioration in performance status)

Considerations

- Patient must have medical drug coverage administered by CDPHP.
- Prior authorization is obtained through the CDPHP pharmacy department.

POLICY EFFECTIVE DATE:	10/1/2025
Policy Control #:	1370/20.000407
Next Annual Review:	March 2027

DISCLAIMER

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgement when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

DESCRIPTION

Technology assessment is the evaluation of a medical or behavioral health procedure, test, therapy, device, or pharmaceutical for safety and efficacy. CDPHP follows a technology review process to determine whether a technology, or new applications to an existing technology, is to be included in its benefit plan.

POLICY NAME: TECHNOLOGY ASSESSMENT & POLICY DEVELOPMENT

POSITION STATEMENT

procedures, pharmaceuticals, and devices. Published scientific evidence must demonstrate a procedure, pharmaceutical, or device is safe and efficacious otherwise it will not be considered eligible for coverage.

CDPHP utilizes **all** of the following criteria to reach decisions regarding eligibility for coverage of new medical and behavioral healthcare procedures, pharmaceuticals and devices, or for new applications to existing technologies:

1. The CDPHP provides systematic and timely review of evolving medical and behavioral health care technology must have final approval from government regulatory bodies.
   - This criteria applies to drugs, biological products, devices, diagnostic technologies, and any other product or procedure that must have final approval to market from the Food and Drug Administration or any other governmental body with authority to regulate the technology.

2. The scientific evidence must permit conclusions concerning the effect of the technology on health outcomes.
   - The evidence should consist of high-quality scientific studies published in peer reviewed journals.
   - The evidence should demonstrate that the technology can measure or alter the physiological changes related to a disease, injury, illness, or condition. In addition, there should be evidence based on established scientific evidence that use of this service affects health outcomes.

3. The technology must improve the net health outcome.
   - The technology's beneficial effects on health outcomes must outweigh any harmful effects on health net outcomes.

4. The technology must be as beneficial as any established alternatives.
   - The technology should improve the net health outcome as much as, or more than, established standard alternative therapies.

5. The technology is not cosmetic in nature and is required for reasons other than convenience.

Technology Review Process

Technology assessment is performed in an ongoing process to evaluate new developments in medical and behavioral healthcare procedures, devices, and pharmaceuticals, as well as new applications to existing technology, to determine eligibility for coverage as non-investigational.

The review of current technology, and its applications, is conducted by the CDPHP technology

assessment team. The team consists of medical directors and medical policy manager(s) with additional appointees as directed. The medical policy manager(s) researches and compiles up-to-date information from computerized searches of the sources of evidence noted below, for review and consideration by the CDPHP technology assessment team. Board certified consultants in medicine and behavioral health may be utilized during the review process when additional expertise is needed regarding a newly emerging medical technology. Final determinations, as to whether a technology meets the above criteria, is based upon the professional assessment of the supporting evidence by the technology assessment team. In addition, the CDPHP medical director may conduct an assessment of a technology for a case specific review, utilizing the same sources of evidence in making the determination. Upon written approval by the CDPHP medical directors, the technology is presented for review, as appropriate, to the policy committee, utilization and management committee, and/or pharmacy and therapeutics committee. Outcomes of a technology assessment team decision may include the development of a new policy, or revision to an existing policy, to address a future covered benefit or to address non-coverage of a reviewed new technology.

Sources of Evidence

- Evidence published in peer-reviewed clinical and scientific literature.
- Opinions and evaluations from professional societies and associations (e.g., American Medical Association, American Psychiatric Association), National Specialty Societies (e.g., American College of Gynecology), consensus panels, or other technology evaluating bodies (e.g., Hayes, Inc., Blue Cross and Blue Shield Association Medical Advisory Panel [MAP]).
- Government agencies such as the U.S. Food and Drug Administration, Centers for Medicare and Medicaid Services, Agency for Healthcare Research and Quality, Center for Disease Control, National Institutes of Health, and the New York State Department of Health.
- Opinions from qualified board-certified consultants in medicine and behavioral health that are supported by scientific evidence.
- Regulatory compliance
- CDPHP physician workgroups.
- Contract language.
- Pharmacists/doctors of pharmacy
- Industry standards (e.g., other payer policies)

The CDPHP technology assessment team determines the effectiveness of the technology based upon scientific evidence demonstrated in published clinical research. Prospective, randomized, and controlled clinical trials are the gold standard of scientific evidence. CDPHP recognizes that this level of evidence is not available to guide treatment decisions for all patients with serious disease. The CDPHP technology assessment team will determine when presented evidence meets generally accepted standards to show that a proposed health service is safe and effective.

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: TECHNOLOGY ASSESSMENT & POLICY DEVELOPMENT

CDPHP Policy Development

CDPHP develops policies relating to health technologies, such as medical, behavioral health and surgical procedures, pharmaceuticals, diagnostic and screening tests, alternative therapies, and medical devices based upon several decision variables including, but not limited to, the following:

- Efficacy and safety
- Experimental status vs. standard of care
- High risk
- High volume
- Issues of controversy
- Medical appropriateness
- Regulatory requirements
- Consistent with CDPHP preventive health and clinical practice guidelines
- Cost effectiveness

The CDPHP medical technology assessment team is responsible for determining the need for an external resource coordination policy, while the Pharmacy and Therapeutics Team is responsible for determining the need for a pharmacy policy. Addition of new policies, deletion of outdated policies, and revision of current policies will be based upon input from enrollees, providers, and staff, as well as current trends in medical treatment and review of current peer reviewed literature. All draft policies are presented to and reviewed by the policy committee with the exception of pharmacy policies which will be presented to and reviewed by the Pharmacy and Therapeutics committee. In addition, draft policies developed to address a new technology or a controversial service, or revisions made to an existing policy, may be sent out to clinicians in the CDPHP network for their expert critique and review.

The policy committee is a multi-disciplinary team consisting of representation from configuration, finance, government programs, member and provider services, utilization management, appeals, behavioral health, healthcare network strategy, business development, self-funded and strategic accounts, commercial sales, claims operation and special investigation unit. It is supported by provider consultants in medicine and behavioral health, and workgroups as needed, to lend clinical expertise to the review activities. After approval by the policy committee, the formal draft is presented to the utilization management committee for review and approval. This committee consists of practicing community physicians appointed by the CDPHP board of directors, who represent a cross section of primary care physicians and specialties from the CDPHP network. Minutes from these respective committees are reported to the quality management committee and board of directors for final approval.

The policy category will be noted on the last page of the policy in order to show the status of the policy after its annual review, as well as the date approved by the utilization management committee or pharmacy and therapeutics committee:

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: TECHNOLOGY ASSESSMENT & POLICY DEVELOPMENT

- New
- Revised - changes made to existing published policy
- Reviewed - no changes made to existing published policy

Resource coordination and pharmacy policies are re-evaluated and updated, as necessary, on an annual basis. Policies may be reviewed prior to their scheduled review date if new scientific evidence that would alter the policy criteria becomes available sooner.

Notification to updates made to resource coordination, behavioral health and pharmacy policies are distributed by mail every other month and are also made available through the CDPHP secure physician interface at www.cdphp.com. An individual policy mailing is performed upon member or provider request, including for those providers who do not have fax, email, or internet access.

- New and revised policies will become effective no less than 90 days from date of distribution.
- Selected policies may be implemented in less than 90 days when allowed for, or not in conflict with, state regulations. For example, 90 days prior notice is not required where the change is required by law or regulation, or required as a result of changes in fee schedules, reimbursement methodology or payment policies established by a government agency, or by a change to a CPT code.

POLICY CONSIDERATIONS

CDPHP reserves the right to change CPT or HCPCS codes in an existing published policy when applicable without 90 days' notice.

The CDPHP technology assessment team will consider technology evaluation requests made by practitioners, or non-participating practitioners who have provided consultation in accordance with the CDPHP Resource Coordination Policy: *Out of Network Care, 1370/20.000145.*

The CDPHP technology assessment team will present a review of current technology literature to the utilization management committee on an as needed basis.

The technology assessment team will maintain files of all reviewed literature.

Decisions are documented in writing at the technology assessment meetings, and minutes are taken at the policy committee, utilization management committee, pharmacy and therapeutics committee meetings to document the date policy issues are discussed.

When necessary, a technology-specific policy will be established through the appropriate committees. Recommended benefit structure changes will be forwarded to the product development team for consideration.

POLICY NAME: TECHNOLOGY ASSESSMENT & POLICY DEVELOPMENT

EXCLUSIONS

CDPHP excludes coverage for any medical or behavioral health care procedure, pharmaceutical, or device that have been determined to be investigational, experimental, unproven, or not medically necessary.

CDPHP PRODUCT VARIATIONS

CHILD HEALTH PLUS	Subject to all terms and conditions noted above in the policy.
MEDICARE ADVANTAGE	Subject to all terms and conditions noted above in the policy to include the following: Clinical criteria contained in the CDPHP resource coordination policies is consistent with general Medicare coverage guidelines, national coverage decisions (NCD), and written local coverage determinations (LCD) of New York State Medicare contractors. Coverage of services includes those covered by original Medicare. Additional coverage may be provided to enrollees above what is offered by original Medicare at the discretion of CDPHP.
SELECT PLAN/HARP	Subject to all terms and conditions noted above in the policy to include the following: Coverage of services contained in a CDPHP policy is consistent with the policy and billing guidance outlined in Medicaid Updates and Medicaid Management information System (MMIS) provider manuals in accordance with New York State Department of Health. Additional coverage may be provided to enrollees above what is offered by the State at the discretion of CDPHP.

POLICY NAME: TEMPOROMANDIBULAR JOINT DISORDERS

POLICY EFFECTIVE DATE:	10/1/2023
Policy Control #:	1370/20.000062
Next Annual Review:	September, 2027

DISCLAIMER

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgement when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

PROCEDURE CODES

20605, 20606, 21010, 21050, 21060, 21070, 21073, 21116, 21240, 21242, 21243, 21480, 21485, 21490, 29800, 29804

DESCRIPTION

Temporomandibular joint disease (TMJ) is defined as any abnormality in joint function that impairs mandibular mobility. Temporomandibular disorders may include internal derangement of the joint and degenerative joint disease. Common symptoms include clicking, grinding, pain or stiffness in the jaw, jaw locking open or closed, muscle spasm, displacement of the joint, and/or difficulty in opening the jaw wide.

RELATED POLICIES/DOCUMENTS

Resource Coordination Policies:

- Orthognathic Surgery, 1370/20.000274
- Physical Therapy, 1370/20.000057

POSITION STATEMENT

CDPHP administers benefits to **confirm a diagnosis** of temporomandibular joint disorder as follows:

- Initial evaluation and radiological procedures

POLICY NAME: TEMPOROMANDIBULAR JOINT DISORDERS

CDPHP administers benefits for the **treatment** of medical related TMJ demonstrated by any of the following conditions:

- Intracapsular pathology caused by systemic illness, such as rheumatoid arthritis or;
- Intracapsular pathology due to internal derangement, such as displacement of temporomandibular joint disc or;
- Documented history of trauma (TMJ related cases involving trauma must have documentation of symptoms occurring within 12 months of the trauma).

CDPHP does not administer benefits for the treatment of dental related TMJ disorders.

POLICY CONSIDERATIONS

The management of medical TMJ disorders includes non-surgical and surgical services as described below.

Non-Surgical Management

Non-surgical management is almost always the initial treatment approach to reduce pain and improve function. Examples of such therapy include:

- Pain management with analgesics or anti-inflammatory medicine.
- Modification of diet and joint activity.
- Intra-oral appliances such as removable splints (all study models are considered global to the surgical splint).
- Improvement of joint mobility with muscle relaxants, physical therapy, and exercises.
- Therapeutic injections (intra-articular and trigger point injections may be used when the above non-invasive treatments do not provide adequate symptom relief).

Surgical Management

CDPHP may provide coverage for the surgical treatment of TMJ disorder when an initial course of covered non-surgical medical treatment has failed to reduce the patient's pain or improve function. Examples of such surgery include, but are not limited to, the following:

- Open or closed reduction of TMJ dislocation or fracture
- Arthocentesis, arthroscopy, arthroplasty, and arthrotomy

Cases of TMJ disease involving intracapsular pathology will be reviewed on an *individual case basis* utilizing medical records to obtain the following clinical information:

- Patient history and non-invasive diagnostic examination.

- TMJ radiographs (transcranial radiographs), MRI, and/or other imaging reports as appropriate.

Cases of TMJ involving displacement of temporomandibular joint disc to include documentation of clinical information as stated above, as well as all of the following criteria:

- Sudden onset of symptoms.
- Documentation of functional limitation of joint range of motion or significant pain unresolved after course of conservative therapy.
- No prior history of temporomandibular joint dysfunction relating to bruxism or malocclusion.

Physical therapy (PT) and durable medical equipment utilized in the treatment of TMJ disorders caused by a documented history of trauma or systemic disease are subject to all terms and conditions of the contracted benefit for the same.

EXCLUSIONS

Any services or supplies related to the treatment of TMJ when it is dental in nature.

Jaw motion rehabilitation systems, such as Therabite or Dynasplint for the treatment of mobility conditions associated with TMJ disorder (E1700, E1701, E1702).

MEDICAL POLICY

Medical Policy Title	**Temporomandibular Joint Disorders (TMJD)**
Policy Number	**11.01.17**
Current Effective Date	**January 1, 2027**
Next Review Date	**January 2028**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

Services related to myofascial pain dysfunction (MPD) are not addressed in this policy as they are rendered by a dentist and considered a dental benefit, rather than a medical benefit.

POLICY STATEMENT(S)

I. Surgical intervention for the treatment of temporomandibular joint disorder is considered **medically appropriate** when **ALL** of the following criteria (P.S. A. B. C. and D.) are met:

A. **ONE (1)** of the following definitions of functional deficit is documented:

1. Presence of pain or other physical deficit that interferes with activities of daily living; or
2. Impaired physical activity (e.g., loss of range of motion);

AND

B. Documentation demonstrates that conservative treatments have been exhausted, with a minimum of six (6) weeks of failed therapy, including dates and duration for **TWO (2) or MORE** of the following*:

1. Medication (e.g., NSAIDS, muscle relaxants or antidepressants);
2. Corticosteroid Injection;
3. Dietary modifications such as a soft diet;
4. Behavioral therapy; or
5. Physical therapy;

*Conservative therapy documentation is not required in the setting of recent trauma, dislocation, severe malocclusion, dental infection or abscess.

AND

C. Documentation includes reports from Magnetic Resonance Imaging (MRI) or Computed Tomography (CT) of the TMJ;

AND

D. The specific documentation requirements for the requested surgery type are met:

1. Arthrocentesis, Arthroscopic Lysis and Lavage, or Operative Arthroscopy (CPT 20605, 20606, 29804)
    a. Imaging reports confirm **any** of the following:
        i. anterior disc displacement with or without reduction;
        ii. disc adhesions;
        iii. synovitis/capsulitis; **or**
        iv. degenerative osteoarthritis; **and**
    b. Physical exam findings are supportive of diagnosis;
2. Open Joint Surgeries (e.g., Arthroplasty or arthrotomy, disc repair procedures, discectomy with or without replacement, condylectomy, discoplasty/disc plication, discectomy/meniscectomy) (CPT 21010, 21050, 21060, 21070, 21240, 21242)
    a. Persistent pain despite previous arthroscopic surgery; **and**
    b. Imaging reports confirm **any** of the following:
        i. internal derangement;
        ii. degenerative joint disease;
        iii. rheumatoid arthritis;
        iv. infectious arthritis;
        v. mandibular dislocation;
        vi. neoplasia;
        vii. ankylosis;
        viii. condylar hyper-or hypoplasia;
        ix. condylar osteolysis; **or**
        x. fracture;
3. Temporomandibular Joint Replacement (CPT 21243):
    a. Imaging reports demonstrate an alteration and degeneration of joint structures at both the bone (e.g., osteophytes, geodes, subchondral cysts) and disc level;
    b. Reduced oral aperture (less than 35mm); **and**
    c. Prior surgeries (i.e., arthroscopy or open) have failed.

POLICY GUIDELINE(S)

I. Coverage for dental-related services is **not** generally provided under medical contracts.

II. Coverage for all TMJD-related services, devices or appliances related to TMJD is contract dependent.

DESCRIPTION

The temporomandibular joint (TMJ) connects the jawbone to the skull, acting like a sliding hinge on either side of the skull. There are more than 30 conditions that cause pain and dysfunction in the jaw joint and the associated muscles that allow for movement. TMJ disorders specifically are broken into three different classes: myofascial pain-dysfunction (MPD) syndrome, internal derangement, and degenerative joint disease (DJD); however, diagnostic criteria are based on subjective findings and patients can fall into more than one class. The U.S. National Institutes of Health acknowledged in 2017 that there are no widely accepted standard tests to correctly diagnosis TMJ disorders.

MPD is considered the most common cause of TMJ pain and is thought to be a psychophysiologic disease that primarily involves the muscles of mastication. Services to treat MPD are rendered by a dentist, and are therefore, not addressed within this policy.

Internal derangement is defined as an abnormal relationship of the articular disc to the mandibular condyle, fossa, and articular eminence. The muscle spasm seen in this condition is in response to the dysfunction; spasm is not the primary problem, as with MPD.

DJD (osteoarthritis) is the organic degeneration of the articular surfaces within the TMJ. It is secondary to micro/macro trauma, infection, and meniscal malalignment.

Diagnosis is typically one of exclusion and requires a combination of physical exam, patient interview, and a review of dental records. Generally, diagnostic testing or imaging are reserved for patients with severe or chronic symptoms.

Patients may experience some or even all of the following symptoms: headaches (over the eye, in

the temples, behind the eyes, and at the base of the skull); general facial pain, and more specific pain directly in front of the ears; ear symptoms, including ringing, buzzing, and congestion; neck and shoulder pain; clicking or grating noises of the joint with movement; locking of the jaw; and pain with function. In severe cases, there can be functional disability, malnutrition, or airway compromise.

The main goals of treatment of TMJ disorder are to reduce or eliminate pain or joint noises, or both, and to restore normal mandibular function. TMJ disorder is a complex disorder with treatment of dependent upon identification of contributing conditions and behaviors, with first-line treatments being conservative in nature due to their low risk of potential side effects.

Arthrocentesis, Arthroscopic Lysis and Lavage

Arthrocentesis is considered a simple, minimally invasive surgery, where the joint space is not viewed, but rather incorporates the use of needles and irrigation to remove inflammatory causes of joint pain and/or to increase the mobility of the mandible by hydraulically removing present adhesions.

Operative Arthroscopy

Arthroscopy of the TMJ is a minimally invasive surgery performed under local anesthesia with sedation or general anesthesia. The joint space is viewed via fiber-optic camera (arthroscope) to diagnose and treat joint problems. The incision is small, and repairs are conducted utilizing thin surgical instruments.

Open Joint Surgeries

Open joint surgery requires a cut to be made in front of the ear, sometimes extending into the hairline to fully expose the jaw joint. It is typically used when needing to alter the shape of the joint (arthroplasty), when minimally invasive surgery was ineffective or for more advanced disease. Open surgery has an increased risk of causing damage to facial nerves and issues with hearing given the proximity to the joint.

Replacement of the Temporomandibular Joint (TMJ)

When conservative therapies have failed, it may be necessary to improve the function of a damaged joint by replacing the bone with a prosthetic. Today's U.S. Food and Drug Administration (FDA) approved joint prosthetics can be stock or custom made. The lower jaw portion of the prosthetic are typically manufactured from metal such as titanium, while the upper jaw portion of the prosthetic is made with ultra-high molecular-weight polyethylene either with or without titanium. Replacement of the TMJ is an open surgery with incisions required in front of the ear, extending to the hairline as well as below the jaw. It is also not without risk, including heterotropic ossification, infection, and chronic post-operative pain.

SUPPORTIVE LITERATURE

Non-Surgical Treatments

Yao et al (2023) conducted a systematic review and meta-analysis of randomized trials in an attempt to provide evidence-based guidelines for adult patients living with moderate chronic pain (4-6cm on a

10cm pain scale for greater than or equal to three months duration) secondary to TMD. This evidence was summarized into a recommendation by Busse et al (2023). The recommendation notes the necessity of the review given the number of interventions available for treatment, that individuals may be exposed to simple, conservative, and inexpensive treatments while others with similar sets of symptoms will be exposed to potentially invasive, irreversible, and costly treatments. As a result of the review, and the limited available evidence, the panel was only able to state confidence regarding the benefits of cognitive behavioral therapy augmented with relaxation or biofeedback, therapist-assisted jaw mobilization, and manual trigger point therapy for reduction in chronic pain severity related to TMJD (GRADE moderate to high certainty of evidence).

Surgical Treatments

Arthrocentesis of the TMJ was introduced in 1991 by Nitzan et al and its use for pain control has been supported by multiple randomized controlled trials (RCTs), systematic reviews of RCTs, as well as observational studies. (e.g., Grossman (2012), Kaneyama et al (2004), Nitzan et al (2001), Emshoff (2005), Carvajal et al (2000), Alpaslan (2003), Frost et al (2012)).

Thorpe et al (2023) conducted a systematic review comparing arthrocentesis versus conservative treatments for TMJD by focusing on joint pain and mouth opening at six-months following the intervention. Studies included in the review were required to meet the following criteria: prospective randomized controlled trial conducted on humans, patients had a history of reduced mouth opening and pain, study included at least one group treated with arthrocentesis and one undergoing conservative therapies, and patients were assessed both preoperatively at recalls for maximum mouth opening and presence of pain with pain assessed via visual analogue scale and allocation being conducted on a per-patient basis. The initial search provided 879 records, with 12 articles selected for full-text analysis, with only seven meeting inclusion criteria. A total of 489 patients were represented in the studies, 448 of which were assessed at the 6-month recall mark. A bias analysis demonstrated that only one study was at low risk of bias. A random-effects model was used for the meta-analysis. Based upon the analysis, authors concluded a statistically significant superiority for arthrocentesis in the improvement of maximal mouth opening and borderline statistical superiority for pain improvement at six-months but note that the confidence interval for pain reduction crossed over zero and that the marginal differences are unlikely to be clinically relevant. Additionally, there was no conservative treatment to be found superior to another.

Tang and colleagues (2025) conducted a systematic review with meta-analysis and trial sequential to compare arthrocentesis to conservative treatments for symptomatic TMJ with short, intermediate, and long-term outcomes of objective measurements, including maximum mouth opening, joint blocks and noises, protrusive and lateral mandibular movements and cost, as well as subjective measurements of joint pain, mandibular function and quality of life (QOL). The intervention group included TMJ arthrocentesis via any technique, with or without concomitant therapies or injections. The control group only consisted of conservative treatments of any kind. The primary study outcome was pain using a numeric scale. Only RCTs, prospective non-randomized controlled trials and retrospective cohort studies with a control group were allowed for inclusion, which resulted in 21 records suitable for inclusion. Of those 21 records, 16 were included in the qualitative and meta-analyses and five were included for the qualitative analyses only. For the primary outcome, for pain

reduction, arthrocentesis was superior to conservative therapy in terms of pain reduction at both short (1-3 months) and intermediate (6-12 months) follow up. Only one RCT reported on pain reduction of long-term follow up (median 6.2 years), Tang et al (2023), which found arthrocentesis was more effective in pain reduction (-10.23 [95% CI -17.86;-2.60], p= 0.009) when compared to conservative treatments. For secondary outcomes, in regard to maximum mouth opening, 11 of 15 studies included in the quantitative analysis demonstrated improvement over time in both the arthrocentesis and conservative treatment groups, while five showed improvements in only the arthrocentesis group. One study demonstrated no statistically significant improvement over time in both groups, with two not adequately reporting differences between pre-and post-operative analysis. Studies assessing outcomes of joint pain at rest, mandibular function, joint bocks and noises, lateral and protrusive movements quality of life and cost were considered too heterogeneous to include in a meta-analysis, but authors concluded that there is a general trend of an equal or superior effect of arthrocentesis when compared to conservative therapies.

Almeida and colleagues (2025) conducted a systematic review to evaluate the long-term quality of life (QOL) outcomes after TMJ replacement, focusing on functional impairment, complication profiles, and differences between custom and stock prosthesis across both adult and pediatric populations. Eligibility criteria included patients undergoing TMJ replacement for end-stage disease (e.g., osteoarthritis, rheumatoid arthritis, juvenile idiopathic arthritis, trauma, ankylosis, condylar resorption, neoplasm). Authors included studies with or without comparator groups as well as any of the following: pre- versus postoperative outcomes, stock versus custom device, or replacement versus other surgical treatment options. Pain reduction (measured by VAS score), functional recovery (measured by maximum interincisal opening [MIO]) and QOL were primary outcomes. Complication rates and the use of advanced technologies were secondary outcomes. Included in the review were randomized controlled trials (RCTs), prospective and retrospective cohort studies and case series with more than five patients. Two reviewers independently conducted a search and out of 950 identified records, 64 were included for qualitative synthesis, representing anywhere from five to 1,262 patients. Follow up periods expanded across six months to over 20 years. Authors reported that TMJ replacement resulted in significant improvements in patient-reported QOL assessed via the SF-36 Health Survey; TMJ-specific patient reported outcome measures, narrative satisfaction reports or structured interviews, reduced pain and disability, improved chewing, speech and diet, enhanced social confidence, sleep quality, and emotional wellbeing. The mean gain of MIO was 26-36 mm, with studies reporting 75-85% reduction in VAS scores (which was consistent between stock and custom prosthesis groups). Regarding complications, an approximate 20% of individuals developed heterotrophic ossification but authors note that when autologous fat grafting was used the rate dropped to below 5%. Infections of the prosthetic were seen in 3-4.9% of cases, Mechanical failure or loosening in roughly 4-5%, chronic pain in 20-30% of cases (often due to central sensitization) and transient facial nerve injury in approximately 10% of cases. Permanent nerve injury occurred in 1-2% of cases. The use of custom prosthetics resulted in slightly higher MIO scores and fit for complex or revision cases while stock prostheses were comparable in pain reduction, QOL, and overall satisfaction in routine cases. Authors reviewed outcomes of pediatric TMJR reporting that there was no clear evidence of mandibular growth inhibition during 2-8 years of follow-up with significant gains in function, chewing, speech and psychosocial well-being identified. The authors

conclude that this systematic review demonstrates TMJ replacement as a highly effective, safe, and durable treatment for end-stage TMJ disorders, which has been noted to consistently provide pain relief, functional improvement, and improved quality of life across varied indications, and across varying populations.

In 2023, the National Institute of Dental and Craniofacial Research (NIDCR), a division of the U.S. National Institute of Health (NIH) called attention to the gaps that remain in understanding the underlying mechanisms of TMJ, and the impact on medical and dental professionals by issuing a notice of funding opportunity to develop a future interdisciplinary research initiative. The goal of the initiative was to improve the prevention, diagnosis, and treatment of temporomandibular disorders (TMD). Nine grants totaling $2.8 million were awarded to begin planning the creation of the TMD Collaborative for Improving Patient-Centered Translational Research (TMD IMPACT). Applications to join the collaboration by higher education institutions, for-profit organizations, non-profit organizations, local and federal governments were accepted through January 2025.

PROFESSIONAL GUIDELINE(S)

In 2018, the American Association of Oral and Maxillofacial Surgeons (AAOMS) published guidelines to evaluate the impairment of the oral and maxillofacial region, including assessment of the temporomandibular joint for permanent impairment using the measurement of the voluntary, non-painful interincisal opening between maxillary and mandibular central incisors to determine the interincisal range of motion, followed by measuring the lateral excursive distance of the mandible, using the dental midlines from maximum dental intercuspation. Adding the values for loss of impairment values of interincisal opening and lateral excursive distance provides the craniomandibular articulation impairment.

In 2024, AAOMS issued a statement about the management of selected clinical conditions and associated clinical procedures for temporomandibular disorders, which includes the diagnostic assessment of TMJ disorders. The statement identifies TMJ disorders being the result of internal derangement, degenerative joint disease, rheumatoid arthritis, infectious arthritis, mandibular dislocation, neoplasia, ankylosis, condylar hyper-or hypoplasia, condylar osteolysis and fractures. Patient historical and physical findings include; unilateral or bilateral pain with or without popping or crepitus, is usually continuous or intermittent and increases with function, is localized to the joint. The mandible can have hypo-or hypermobility. AAOMS includes imaging (e.g., plain, or tomographic TMJ radiographs, CT, MRI, three-dimensional imaging) and appropriate laboratory testing such as a rheumatoid panel. The guidelines suggest that non-surgical management includes "medication (e.g., NSAIDs), orthotic appliance, and physical therapy", while surgical treatments include "manipulation under anesthesia, arthrocentesis, non-arthroscopic lysis and lavage, arthroscopic surgery, open arthroplasty with or without autograft, open arthroplasty with alloplast, disc repair or removal (with or without replacement), coronoidectomy, condylectomy, mandibular condylotomy, myotomy, orthognathic surgery, partial or total reconstruction". The therapeutic outcomes include "a level of pain that is of little or no concern to the patient, improved jaw function, improved ability to masticate food, functional and stable occlusion, limited period of disability, acceptable clinical appearance, absence of recurrent jaw locking or dislocation, limited progression of the disease, and in growing children, continued symmetrical growth of the mandible in proper relationship to the midface."

The American Society of Temporomandibular Surgeons (ASTMJS) is a non-profit organization comprised of maxillofacial, orthopedic, plastic/reconstructive, and oral surgical specialists. The ASTMJS website (2025) includes parameters and guidelines for treatment, stating the following "In the United States, the NIH has estimated that 10 million Americans have painful TMJ dysfunction, the majority of which are self-limiting or respond to non-surgical treatment. As in orthopedic management of other joint systems of the body, anti-inflammatory medication, physical therapy, orthotics or splints, and rest are usually sufficient initial treatment modalities. However, the time given to initial treatment must be finite when such treatment proves to be ineffective, or the clinical condition deteriorates. Surgical procedures are indicated when pre-surgical imaging studies confirm pathologic and structural changes of the joint that creates significant pain dysfunction and impairment."

For more information, refer to the ASTMJS website, available from: https://astmjs.org/tmd-general-information/ [accessed 2025 Oct 14].

REGULATORY STATUS

The United States Food and Drug Administration (FDA) regulates temporomandibular joint prosthetics as medical devices. All TMJ prosthetics require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2025 Oct 14]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most serious type of recalls. Available from: Medical Device Recalls | FDA [accessed 2025 Oct 14]

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).

CENTERS FOR MEDICARE AND MEDICAID SERVICES (CMS)

Temporomandibular joint dysfunction is not addressed in National or Regional Medicare coverage determinations or policies. However, treatment of TMJ syndrome is addressed in the chapter addressing Covered Medical and Other Health Services, Section 150.1, in the Medicare Benefit Policy Manual. Please refer to the following website for Medicare members:

https://www.cms.gov/Regulations-and-Guidance/Guidance/Manuals/Downloads/bp102c15.pdf [accessed 2025 Oct 22].

PRODUCT DISCLAIMER

- Services are contract dependent; if a product does not cover a service, medical policy criteria do not apply.
- If a commercial product (including an Essential Plan or Child Health Plus product) covers a

specific service, medical policy criteria apply to the benefit.

- If a Medicaid product covers a specific service, and there are no New York State Medicaid guidelines (eMedNY) criteria, medical policy criteria apply to the benefit.
- If a Medicare product covers a specific service, and there is no national or local Medicare coverage decision for the service, medical policy criteria apply to the benefit.

Committee Approval Dates	
01/01/27	
Date	**Summary of Changes**
01/01/27	• Original effective date

MEDICAL POLICY

Medical Policy Title	**Temporomandibular Joint Disorders (TMJD)**
Policy Number	**11.01.17**
Current Effective Date	**February 15, 2027**
Next Review Date	**October 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service.
(Link to Product Disclaimer)

Services related to myofascial pain dysfunction (MPD) are not addressed in this policy as they are rendered by a dentist and considered a dental benefit, rather than a medical benefit.

POLICY STATEMENT(S)

I. Non-surgical intervention (e.g. oral appliances) for the treatment of temporomandibular joint disorder is considered **medically appropriate** when **ALL** of the following criteria (P.S. A. B. C. and D.) are met:

A. **ONE (1)** of the following definitions of functional deficit is documented:

1. Presence of pain or other physical deficit that interferes with activities of daily living; or
2. Impaired physical activity (e.g., loss of range of motion);

AND

B. Documentation demonstrates that conservative treatments have been exhausted, with a minimum of six (6) weeks of failed therapy, including dates and duration for **TWO (2) or MORE** of the following*:

1. Medication (e.g., NSAIDS, muscle relaxants or antidepressants);
2. Corticosteroid Injection;
3. Dietary modifications such as a soft diet;
4. Behavioral therapy; or
5. Physical therapy;

*Conservative therapy documentation is not required in the setting of recent trauma, dislocation, severe malocclusion, dental infection or abscess.

AND

C. Documentation includes reports from Magnetic Resonance Imaging (MRI) or Computed Tomography (CT) of the TMJ;

AND

D. The specific documentation requirements for the requested non-surgical treatment are met:
   1. Imaging reports confirm **any** of the following:
      a. anterior disc displacement with or without reduction;
      b. disc adhesions;
      c. synovitis/capsulitis;
      d. degenerative osteoarthritis;
      e. internal derangement;
      f. degenerative joint disease;
      g. rheumatoid arthritis;
      h. infectious arthritis;
      i. mandibular dislocation;
      j. neoplasia;
      k. ankylosis;
      l. condylar hyper-or hypoplasia; **or**
      m. condylar osteolysis

II. Surgical intervention for the treatment of temporomandibular joint disorder is considered **medically appropriate** when **ALL** of the following criteria (P.S. A. B. C. and D.) are met:

A. **ONE (1)** of the following definitions of functional deficit is documented:
   1. Presence of pain or other physical deficit that interferes with activities of daily living; or
   2. Impaired physical activity (e.g., loss of range of motion);

AND

B. Documentation demonstrates that conservative treatments have been exhausted, with a minimum of six (6) weeks of failed therapy, including dates and duration for **TWO (2) or MORE** of the following*:
   1. Medication (e.g., NSAIDS, muscle relaxants or antidepressants);
   2. Corticosteroid Injection;
   3. Dietary modifications such as a soft diet;
   4. Behavioral therapy; or
   5. Physical therapy;

*Conservative therapy documentation is not required in the setting of recent trauma, dislocation, severe malocclusion, dental infection or abscess.

AND

C. Documentation includes reports from Magnetic Resonance Imaging (MRI) or Computed Tomography (CT) of the TMJ;

AND

D. The specific documentation requirements for the requested surgery type are met:

1. Arthrocentesis, Arthroscopic Lysis and Lavage, or Operative Arthroscopy (CPT 20605, 20606, 29804)
    a. Imaging reports confirm **any** of the following:
        i. anterior disc displacement with or without reduction;
        ii. disc adhesions;
        iii. synovitis/capsulitis; **or**
        iv. degenerative osteoarthritis; **and**
    b. Physical exam findings are supportive of diagnosis;
2. Open Joint Surgeries (e.g., Arthroplasty or arthrotomy, disc repair procedures, discectomy with or without replacement, condylectomy, discoplasty/disc plication, discectomy/meniscectomy) (CPT 21010, 21050, 21060, 21070, 21240, 21242)
    a. Persistent pain despite previous arthroscopic surgery; **and**
    b. Imaging reports confirm **any** of the following:
        i. internal derangement;
        ii. degenerative joint disease;
        iii. rheumatoid arthritis;
        iv. infectious arthritis;
        v. mandibular dislocation;
        vi. neoplasia;
        vii. ankylosis;
        viii. condylar hyper-or hypoplasia;
        ix. condylar osteolysis; **or**
        x. fracture;
3. Temporomandibular Joint Replacement (CPT 21243):
    a. Imaging reports demonstrate an alteration and degeneration of joint structures at both the bone (e.g., osteophytes, geodes, subchondral cysts) and disc level;

b. Reduced oral aperture (less than 35mm); **and**

c. Prior surgeries (i.e., arthroscopy or open) have failed.

Device Repair

III. Repair of a medically necessary [device] or components not under warranty will be considered **medically appropriate** when the following criteria are met:

A. Physician documentation includes **ALL** of the following:

1. date of device implantation/initiation;
2. manufacturer warranty information, if applicable;
3. attestation that the patient has been compliant with the use of device and will continue to benefit from the use of device;

B. The device is no longer functioning adequately; and **BOTH** of the following criteria are met:

1. inadequate function interferes with activities of daily living; **and**
2. repair is expected to make the equipment fully functional (as defined by manufacturer).

IV. Repair of equipment damaged due to patient neglect, theft, abuse, or when another available coverage source is an option (e.g., homeowners, rental, auto, liability insurance, etc.) is **ineligible for coverage**.

Device Replacement

V. Replacement of a medically necessary [device] or components not under warranty will be considered **medically appropriate** when **EITHER** of the following criteria are met:

A. The device is no longer functioning adequately and has been determined to be non-repairable, or the cost of the repair is in excess of the replacement cost;

B. There is documentation that a change in the patient's condition makes the present unit non-functional and improvement is expected with a replacement unit.

VI. The replacement of a properly functioning [device], its components or accessories is considered **not medically necessary**. This includes, but is not limited to, replacement desired due to advanced technology or in order to make the device more aesthetically pleasing;

VII. The replacement of equipment damaged or lost due to patient neglect, theft, abuse, or when another available coverage source is an option (e.g., homeowners, rental, auto, liability insurance, etc.) is **ineligible for coverage**.

VIII. Accessories or components for [device] that are considered not medically necessary or investigational by peer-reviewed literature will also be considered as **not medically necessary or investigational** by the Health Plan.

POLICY GUIDELINE(S)

I. Coverage for dental-related services is **not** generally provided under medical contracts.

II. Coverage for all TMJD-related services, devices or appliances related to TMJD is contract dependent.

DESCRIPTION

The temporomandibular joint (TMJ) connects the jawbone to the skull, acting like a sliding hinge on either side of the skull. There are more than 30 conditions that cause pain and dysfunction in the jaw joint and the associated muscles that allow for movement. TMJ disorders specifically are broken into three different classes: myofascial pain-dysfunction (MPD) syndrome, internal derangement, and degenerative joint disease (DJD); however, diagnostic criteria are based on subjective findings and patients can fall into more than one class. The U.S. National Institutes of Health acknowledged in 2017 that there are no widely accepted standard tests to correctly diagnosis TMJ disorders.

MPD is considered the most common cause of TMJ pain and is thought to be a psychophysiologic disease that primarily involves the muscles of mastication. Services to treat MPD are rendered by a dentist, and are therefore not addressed within this policy.

Internal derangement is defined as an abnormal relationship of the articular disc to the mandibular condyle, fossa, and articular eminence. The muscle spasm seen in this condition is in response to the dysfunction; spasm is not the primary problem, as with MPD.

DJD (osteoarthritis) is the organic degeneration of the articular surfaces within the TMJ. It is secondary to micro/macro trauma, infection, and meniscal malalignment.

Diagnosis is typically one of exclusion and requires a combination of physical exam, patient interview, and a review of dental records. Generally, diagnostic testing or imaging are reserved for patients with severe or chronic symptoms.

Patients may experience some or even all of the following symptoms: headaches (over the eye, in the temples, behind the eyes, and at the base of the skull); general facial pain, and more specific pain directly in front of the ears; ear symptoms, including ringing, buzzing, and congestion; neck and shoulder pain; clicking or grating noises of the joint with movement; locking of the jaw; and pain with function. In severe cases, there can be functional disability, malnutrition, or airway compromise.

The main goals of treatment of TMJ disorder are to reduce or eliminate pain or joint noises, or both, and to restore normal mandibular function. TMJ disorder is a complex disorder with treatment of dependent upon identification of contributing conditions and behaviors, with first-line treatments being conservative in nature due to their low risk of potential side effects.

Arthrocentesis, Arthroscopic Lysis and Lavage

Arthrocentesis is considered a simple, minimally invasive surgery, where the joint space is not viewed, but rather incorporates the use of needles and irrigation to remove inflammatory causes of joint pain and/or to increase the mobility of the mandible by hydraulically removing present adhesions.

Operative Arthroscopy

Arthroscopy of the TMJ is a minimally invasive surgery performed under local anesthesia with sedation or general anesthesia. The joint space is viewed via fiber-optic camera (arthroscope) to diagnose and treat joint problems. The incision is small, and repairs are conducted utilizing thin surgical instruments.

Open Joint Surgeries

Open joint surgery requires a cut to be made in front of the ear, sometimes extending into the hairline to fully expose the jaw joint. It is typically used when needing to alter the shape of the joint (arthroplasty), when minimally invasive surgery was ineffective or for more advanced disease. Open surgery has an increased risk of causing damage to facial nerves and issues with hearing given the proximity to the joint.

Replacement of the Temporomandibular Joint (TMJ)

When conservative therapies have failed, it may be necessary to improve the function of a damaged joint by replacing the bone with a prosthetic. Today's U.S. Food and Drug Administration (FDA) approved joint prosthetics can be stock or custom made. The lower jaw portion of the prosthetic are typically manufactured from metal such as titanium, while the upper jaw portion of the prosthetic is made with ultra-high molecular-weight polyethylene either with or without titanium. Replacement of the TMJ is an open surgery with incisions required in front of the ear, extending to the hairline as well as below the jaw. It is also not without risk, including heterotropic ossification, infection, and chronic post-operative pain.

SUPPORTIVE LITERATURE

Non-Surgical Treatments

Yao et al (2023) conducted a systematic review and meta-analysis of randomized trials in an attempt to provide evidence-based guidelines for adult patients living with moderate chronic pain (4-6cm on a 10cm pain scale for greater than or equal to three months duration) secondary to TMD. This evidence was summarized into a recommendation by Busse et al (2023). The recommendation notes the necessity of the review given the number of interventions available for treatment, that individuals may be exposed to simple, conservative, and inexpensive treatments while others with similar sets of symptoms will be exposed to potentially invasive, irreversible, and costly treatments. As a result of the review, and the limited available evidence, the panel was only able to state confidence regarding the benefits of cognitive behavioral therapy augmented with relaxation or biofeedback, therapist-assisted jaw mobilization, and manual trigger point therapy for reduction in chronic pain severity related to TMJD (GRADE moderate to high certainty of evidence).

Surgical Treatments

Arthrocentesis of the TMJ was introduced in 1991 by Nitzan et al and its use for pain control has been supported by multiple randomized controlled trials (RCTs), systematic reviews of RCTs, as well as observational studies. (e.g., Grossman (2012), Kaneyama et al (2004), Nitzan et al (2001), Emshoff (2005), Carvajal et al (2000), Alpaslan (2003), Frost et al (2012)).

Thorpe et al (2023) conducted a systematic review comparing arthrocentesis versus conservative treatments for TMJD by focusing on joint pain and mouth opening at six months following the intervention. Studies included in the review were required to meet the following criteria: prospective randomized controlled trial conducted on humans, patients had a history of reduced mouth opening and pain, study included at least one group treated with arthrocentesis and one undergoing conservative therapies, and patients were assessed both preoperatively at recalls for maximum mouth opening and presence of pain with pain assessed via visual analogue scale and allocation being conducted on a per-patient basis. The initial search provided 879 records, with 12 articles selected for full-text analysis, with only seven meeting inclusion criteria. A total of 489 patients were represented in the studies, 448 of which were assessed at the 6-month recall mark. A bias analysis demonstrated that only one study was at low risk of bias. A random-effects model was used for the meta-analysis. Based upon the analysis, authors concluded a statistically significant superiority for arthrocentesis in the improvement of maximal mouth opening and borderline statistical superiority for pain improvement at six-months but note that the confidence interval for pain reduction crossed over zero and that the marginal differences are unlikely to be clinically relevant. Additionally, there was no conservative treatment to be found superior to another.

Tang and colleagues (2025) conducted a systematic review with meta-analysis and trial sequential to compare arthrocentesis to conservative treatments for symptomatic TMJ with short, intermediate, and long-term outcomes of objective measurements, including maximum mouth opening, joint blocks and noises, protrusive and lateral mandibular movements and cost, as well as subjective measurements of joint pain, mandibular function and quality of life (QOL). The intervention group

included TMJ arthrocentesis via any technique, with or without concomitant therapies or injections. The control group only consisted of conservative treatments of any kind. The primary study outcome was pain using a numeric scale. Only RCTs, prospective non-randomized controlled trials and retrospective cohort studies with a control group were allowed for inclusion, which resulted in 21 records suitable for inclusion. Of those 21 records, 16 were included in the qualitative and meta-analyses and five were included for the qualitative analyses only. For the primary outcome, for pain reduction, arthrocentesis was superior to conservative therapy in terms of pain reduction at both short (1-3 months) and intermediate (6-12 months) follow up. Only one RCT reported on pain reduction of long-term follow up (median 6.2 years), Tang et al (2023), which found arthrocentesis was more effective in pain reduction (-10.23 [95% CI -17.86;-2.60], p= 0.009) when compared to conservative treatments. For secondary outcomes, in regard to maximum mouth opening, 11 of 15 studies included in the quantitative analysis demonstrated improvement over time in both the arthrocentesis and conservative treatment groups, while five showed improvements in only the arthrocentesis group. One study demonstrated no statistically significant improvement over time in both groups, with two not adequately reporting differences between pre-and post-operative analysis. Studies assessing outcomes of joint pain at rest, mandibular function, joint bocks and noises, lateral and protrusive movements quality of life and cost were considered too heterogeneous to include in a meta-analysis, but authors concluded that there is a general trend of an equal or superior effect of arthrocentesis when compared to conservative therapies.

Almeida and colleagues (2025) conducted a systematic review to evaluate the long-term quality of life (QOL) outcomes after TMJ replacement, focusing on functional impairment, complication profiles, and differences between custom and stock prosthesis across both adult and pediatric populations. Eligibility criteria included patients undergoing TMJ replacement for end-stage disease (e.g., osteoarthritis, rheumatoid arthritis, juvenile idiopathic arthritis, trauma, ankylosis, condylar resorption, neoplasm). Authors included studies with or without comparator groups as well as any of the following: pre- versus postoperative outcomes, stock versus custom device, or replacement versus other surgical treatment options. Pain reduction (measured by VAS score), functional recovery (measured by maximum interincisal opening [MIO]) and QOL were primary outcomes. Complication rates and the use of advanced technologies were secondary outcomes. Included in the review were randomized controlled trials (RCTs), prospective and retrospective cohort studies and case series with more than five patients. Two reviewers independently conducted a search and out of 950 identified records, 64 were included for qualitative synthesis, representing anywhere from five to 1,262 patients. Follow-up periods expanded across six months to over 20 years. Authors reported that TMJ replacement resulted in significant improvements in patient-reported QOL assessed via the SF-36 Health Survey; TMJ-specific patient reported outcome measures, narrative satisfaction reports or structured interviews, reduced pain and disability, improved chewing, speech and diet, enhanced social confidence, sleep quality, and emotional wellbeing. The mean gain of MIO was 26-36 mm, with studies reporting 75-85% reduction in VAS scores (which was consistent between stock and custom prosthesis groups). Regarding complications, an approximate 20% of individuals developed heterotrophic ossification but authors note that when autologous fat grafting was used the rate dropped to below 5%. Infections of the prosthetic were seen in 3-4.9% of cases, Mechanical failure or loosening in roughly 4-5%, chronic pain in 20-30% of cases (often due to central sensitization)

and transient facial nerve injury in approximately 10% of cases. Permanent nerve injury occurred in 1-2% of cases. The use of custom prosthetics resulted in slightly higher MIO scores and fit for complex or revision cases while stock prostheses were comparable in pain reduction, QOL, and overall satisfaction in routine cases. Authors reviewed outcomes of pediatric TMJR reporting that there was no clear evidence of mandibular growth inhibition during 2-8 years of follow-up with significant gains in function, chewing, speech and psychosocial well-being identified. The authors conclude that this systematic review demonstrates TMJ replacement as a highly effective, safe, and durable treatment for end-stage TMJ disorders, which has been noted to consistently provide pain relief, functional improvement, and improved quality of life across varied indications, and across varying populations.

In 2023, the National Institute of Dental and Craniofacial Research (NIDCR), a division of the U.S. National Institute of Health (NIH) called attention to the gaps that remain in understanding the underlying mechanisms of TMJ, and the impact on medical and dental professionals by issuing a notice of funding opportunity to develop a future interdisciplinary research initiative. The goal of the initiative was to improve the prevention, diagnosis, and treatment of temporomandibular disorders (TMD). Nine grants totaling $2.8 million were awarded to begin planning the creation of the TMD Collaborative for Improving Patient-Centered Translational Research (TMD IMPACT). Applications to join the collaboration by higher education institutions, for-profit organizations, non-profit organizations, local and federal governments were accepted through January 2025.

PROFESSIONAL GUIDELINE(S)

In 2018, the American Association of Oral and Maxillofacial Surgeons (AAOMS) published guidelines to evaluate the impairment of the oral and maxillofacial region, including assessment of the temporomandibular joint for permanent impairment using the measurement of the voluntary, non-painful interincisal opening between maxillary and mandibular central incisors to determine the interincisal range of motion, followed by measuring the lateral excursive distance of the mandible, using the dental midlines from maximum dental intercuspation. Adding the values for loss of impairment values of interincisal opening and lateral excursive distance provides the craniomandibular articulation impairment.

In 2024, AAOMS issued a statement about the management of selected clinical conditions and associated clinical procedures for temporomandibular disorders, which includes the diagnostic assessment of TMJ disorders. The statement identifies TMJ disorders being the result of internal derangement, degenerative joint disease, rheumatoid arthritis, infectious arthritis, mandibular dislocation, neoplasia, ankylosis, condylar hyper-or hypoplasia, condylar osteolysis and fractures. Patient historical and physical findings include; unilateral or bilateral pain with or without popping or crepitus, is usually continuous or intermittent and increases with function, is localized to the joint. The mandible can have hypo-or hypermobility. AAOMS includes a history, screening and physical, imaging (e.g., plain, or tomographic TMJ radiographs, CT, MRI, three-dimensional imaging), appropriate laboratory testing such as a rheumatoid panel and initiating the least invasive therapy for treatment. The guidelines suggest that non-surgical management includes "medication (e.g., NSAIDs), orthotic appliance, and physical therapy", while surgical treatments include "manipulation

under anesthesia, arthrocentesis, non-arthroscopic lysis and lavage, arthroscopic surgery, open arthroplasty with or without autograft, open arthroplasty with alloplast, disc repair or removal (with or without replacement), coronoidectomy, condylectomy, mandibular condylotomy, myotomy, orthognathic surgery, partial or total reconstruction". The therapeutic outcomes include "a level of pain that is of little or no concern to the patient, improved jaw function, improved ability to masticate food, functional and stable occlusion, limited period of disability, acceptable clinical appearance, absence of recurrent jaw locking or dislocation, limited progression of the disease, and in growing children, continued symmetrical growth of the mandible in proper relationship to the midface."

The American Society of Temporomandibular Surgeons (ASTMJS) is a non-profit organization comprised of maxillofacial, orthopedic, plastic/reconstructive, and oral surgical specialists. The ASTMJS website (2025) includes parameters and guidelines for treatment, stating the following "In the United States, the NIH has estimated that 10 million Americans have painful TMJ dysfunction, the majority of which are self-limiting or respond to non-surgical treatment. As in orthopedic management of other joint systems of the body, anti-inflammatory medication, physical therapy, orthotics or splints, and rest are usually sufficient initial treatment modalities. However, the time given to initial treatment must be finite when such treatment proves to be ineffective, or the clinical condition deteriorates. Surgical procedures are indicated when pre-surgical imaging studies confirm pathologic and structural changes of the joint that creates significant pain dysfunction and impairment."

For more information, refer to the ASTMJS website, available from: https://astmjs.org/tmd-general-information/ [accessed 2026 Jul 26].

REGULATORY STATUS

The United States Food and Drug Administration (FDA) regulates temporomandibular joint prosthetics as medical devices. All TMJ prosthetics require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2026 Jul 27]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most serious type of recalls. Available from: Medical Device Recalls | FDA [accessed 2026 Jul 27]

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
20605	Arthrocentesis, aspiration and/or injection, intermediate joint or burse (e.g., temporomandibular, acromioclavicular, wrist, elbow, or ankle, olecranon bursa); without ultrasound guidance
20606	with ultrasound guidance, with permanent recording and reporting
21010	Arthrotomy, temporomandibular joint
21050	Condylectomy, temporomandibular joint (separate procedure)
21060	Meniscectomy, partial or complete, temporomandibular joint
21070	Coronoidectomy (separate procedure)
21073	Manipulation of the temporomandibular joint(s) (TMJ), therapeutic, requiring an anesthesia service (i.e., general or monitored anesthesia care)
21240	Arthroplasty, temporomandibular joint, with or without autograft (includes obtaining graft)
21242	Arthroplasty, temporomandibular joint, with allograft
21243	Arthroplasty, temporomandibular joint, with prosthetic joint replacement
21299	Unlisted craniofacial and maxillofacial procedure
21480	Closed treatment of temporomandibular dislocation; initial or subsequent
21485	complicated (e.g., recurrent requiring intermaxillary fixation or splinting), initial or subsequent
21490	Open treatment of temporomandibular dislocation
29800	Arthroscopy, temporomandibular joint, diagnostic, with or without synovial biopsy (separate procedure)
29804	Arthroscopy, temporomandibular joint, surgical

CDPHP reserves the right to review this policy at any time and change it without notice.

Background

Tepezza (teprotumumab-trbw) is an insulin-like growth-factor-1 receptor inhibitor indicated for the treatment of thyroid eye disease (TED). Tepezza is a fully human IgG1 monoclonal antibody, with a mechanism of action that is not fully characterized, though its binding blocks activation of the IGF-1R and subsequent signaling. This is the first FDA-approved drug for the treatment of TED (also referred to as Graves' orbitopathy). Graves' disease affects approximately one to two percent of the U.S. population. Approximately 20–25 percent of those with the condition also have TED, and among them about five percent have moderate to severe TED disease.

TED is an autoimmune condition of the retroorbital tissues. The result is inflammation and tissue expansion behind the eye, leading to proptosis (bulging eye), which is accompanied by pain and diplopia (swelling/stiffness of the muscles that move the eye, progressing so that the eyes can no longer move in line with each other), and in the most severe cases, blindness. The condition of TED occurs very often alongside Graves' disease. In the vast majority of cases that are considered mild, the symptoms appear as mild to moderate eyelid swelling, proptosis < 3 mm above the upper limit of normal for race, with no or intermittent diplopia and corneal exposure responsive to lubricants. Moderate to severe symptoms include inflamed eyes with increasing diplopia or proptosis ≥ 3 mm above the upper limit of normal for race, and a spectrum of mild corneal irritation to ulceration from overexposure.

The approach to treatment of TED should be reversal of hyperthyroidism (and resultant hypothyroidism as a consequence of hyperthyroidism therapy), if present. Additional treatment approaches include smoking cessation, local measures to reduce ocular surface irritation, and therapy to reduce inflammation/swelling in the periorbital tissues. In mild cases, local measures often provide sufficient relief of symptoms, and even selenium or non-steroidal anti-inflammatory drugs may be considered. Moderate to severe cases should first be treated with systemic glucocorticoids (GCs). If a contraindication, intolerance, or lack of response exists to GCs, other options include alternative medical therapies (teprotumumab included), external orbital radiation, or orbital decompression surgery. The 2016 European Thyroid Association/European Group on Graves' Orbitopathy Guidelines for the Management of Graves' Orbitopathy advises that for moderate-to-severe cases of TED, high-dose GCs, preferably via the intravenous route, are the first line for treatment with optional cumulative doses of 4.5-5 g of methylprednisolone, but higher doses (up to 8 g) can be used for more severe forms. Second-line therapy options include a second round of GCs as they are efficacious; however, partial or inadequate responses or recurrences are not uncommon, and this should be done only if the cumulative dose of 8 g of methylprednisolone has not been reached.

Tepezza was evaluated in two randomized, placebo-controlled trials.[6,7] The Phase 3 OPTIC trial was similar in design and endpoints to the Phase 2 predecessor. OPTIC enrolled 83 patients with moderate to severe active TED every three weeks for a total of eight doses, with a final evaluation at 24 weeks. The baseline mean proptosis measurement for the teprotumumab arm was 22.62 mm, and 23.2 mm in the placebo group. The primary outcome was a reduction in proptosis of ≥ 2 mm at week 24.[7] Several secondary outcomes were measured, and included an overall response (reduction ≥ 2 points in clinical activity score [CAS] plus reduction in proptosis of ≥ 2 mm), mean change in proptosis, a clinical activity score of 0 or 1 (no or minimal inflammation), and results of the Graves' ophthalmopathy-specific quality-of-life questionnaire (GO-QOL).[6,7] At week 24, the proptosis response was higher in the active-treatment arm compared to placebo (83% [n-34] versus 10% [n-4], P < 0.001) with a number needed to treat of 1.36.[7] Secondary outcomes all statistically significantly favored therapy over placebo, including an overall response of 78% (n-32) versus 7% (n-3), mean change in proptosis (-2.82 mm versus 0.54 mm), and CAS of 0-1 (59% versus 21%). Lastly, the mean change in GO-QOL was improved in the treatment arm over placebo (13.79 points versus 4.43 points, P ≤ 0.001).[7] Adverse effects were noted, and occurred in less than 5% of the studied population. Adverse effects of interest include development of hyperglycemia (n-2), transient hearing impairment and hearing loss, and weight loss of at least 5 kilograms.[7] Two serious adverse effects were described: pneumothorax (determined to be unrelated), and an infusion reaction that led to withdrawal from the trial.

Lumvoa, an insulin-like growth factor-1 receptor (IGF-1R) inhibitor, is indicated for the treatment of thyroid eye disease regardless of thyroid eye disease activity or duration. The efficacy of Lumvoa was evaluated in two randomized, double-blind, placebo-controlled, Phase III pivotal studies (THRIVE and THRIVE-2). Both studies enrolled patients ≥ 18 years of age with moderate to severe thyroid eye disease. THRIVE enrolled patients with active disease (clinical activity score [CAS] ≥ 3) and disease onset < 15 months of screening. THRIVE-2 enrolled patients with any CAS (range 0 to 7) and disease onset > 15 months. Selected patients with prior orbital decompression surgery were allowed to participate but patients with hearing impairment were excluded from both studies. Key efficacy endpoints were the same for both trials and were the proptosis responder rate (defined as the proportion of patients with ≥ 2 mm reduction in proptosis in the study eye from baseline without deterioration in proptosis [≥ 2 mm increase] in the non-study eye) at Week 15 and the mean change in proptosis

from baseline to Week 15. In both studies, the proptosis responder rate at Week 15 and the mean change in proptosis from baseline to Week 15 were significantly greater in the Lumvoa group vs. placebo.

Summary	
Effective date of policy:	8/28/2026
Indications	Thyroid eye disease
Availability	Tepezza: 500 mg/10.5 ml (47.6 mg/mL) Lumvoa: 500 mg/10 mL single-dose vials
HCPCS	Tepezza: J3241 Lumvoa: No specific code

Required Criteria for Approval

All of the following conditions for the requested indication must be met in order to approve Tepezza therapy:

Drug	Criteria
Tepezza (teprotumumab)	1. Member must be at least 18 years old AND 2. Must be prescribed by an endocrinologist or ophthalmologist AND 3. Must have a diagnosis of thyroid eye disease (TED) AND 4. Must have moderate-to-severe TED defined as one of the following (a, b, c, or d): a. Lid retraction ≥ 2 mm b. Moderate to severe soft tissue involvement c. Proptosis > 3 mm above normal for race and sex (see Appendix) d. Diplopia AND 5. Documentation within the past 12 months must be provided to indicate one of the following (a or b): a. Patient is euthyroid prior to starting treatment OR b. Patient has mild hypo- or hyperthyroidism defined as a free thyroxine (T4) or free triiodothyronine (T3) levels less than 50% above or below the normal limits AND patient is currently receiving treatment to correct thyroid levels AND 6. Must not have been previously treated with an IGF-1 receptor inhibitor (e.g., Lumvoa (veligrotug), Tepezza (teprotumumab)) 7. Retreatment is considered not medically necessary and will not be covered based on currently available literature 8. FDA approved dosing is 10 mg/kg for the first infusion, followed by 20 mg/kg every 3 weeks for 7 additional infusions. a. If the prescriber agrees to dose rounding, then the approved dose may be rounded down to the nearest 500 mg vial if the resulting reduction is less than or equal to 10% of the calculated FDA-approved weight-based dose. This applies to all lines of business for new starts only. 9. Approval will be for 7 months to allow for 8 infusions total.
Lumvoa (veligrotug)	1. Must be 18 years of age or older 2. Must be prescribed by an endocrinologist or ophthalmologist **AND** 3. Must have a diagnosis of thyroid eye disease (TED) **AND** 4. Must have documentation of moderate-to-severe TED defined as **<u>one</u>** of the following (a, b, c, or d): a. Lid retraction <u>≥</u> 2 mm b. Moderate to severe soft tissue involvement c. Proptosis <u>≥</u> 3 mm above normal for race and sex (see Considerations) d. Diplopia **AND** **5.** Documentation within the past 12 months must be provided to indicate one of the following (a or b): **a.** Patient is euthyroid prior to starting treatment **OR** **b.** Patient has mild hypo- or hyperthyroidism defined as a free thyroxine (T4) or free triiodothyronine (T3) levels less than 50% above or below the normal limits **AND** patient is currently receiving treatment to correct thyroid levels **AND** 6. Must not have been previously treated with an IGF-1 receptor inhibitor (e.g., Lumvoa (veligrotug), Tepezza (teprotumumab)) 7. Retreatment is considered experimental/investigational 8. FDA approved dosing is 10 mg/kg every three weeks for a total of 5 infusions

a. If the prescriber agrees to dose rounding, then the approved dose may be rounded down to the nearest 500 mg vial if the resulting reduction is less than or equal to 10% of the calculated FDA-approved weight-based dose. This applies to all lines of business for new starts only.

9. Approval will be for 6 months to allow for 5 infusions total given every 3 weeks

Considerations

Prior authorization is obtained through the CDPHP pharmacy department.

Proptosis upper limit of normal by race and sex		
	Female	Male
White	19 mm	21 mm
African American	23 mm	24 mm
Chinese	18 mm	19 mm
Thai	16 mm	17 mm

CDPHP Pharmacy Services 8/28/2026

New: 4/2020

Revised	Reviewed
9/2021, 4/2022, 4/2025, 9/2025	4/2021, 4/2023, 4/2024

Revision Date	Changes Made
9/2021	Removed requirement for prior corticosteroid therapy, removed exclusion of prior surgical treatment or orbital irradiation for TED
4/2022	Changed Inclusion Criteria from "Enrollee does not smoke" to: If enrollee is currently smoking, enrollee has been counseled by requesting provider of the importance of smoking cessation, as smoking is known to worsen Graves hyperthyroidism/TED Changed Exclusion Criteria from "Enrollee has received previous treatment with Rituximab or Tocilizumab" to state Enrollee is not currently utilizing another biologic immunomodulator
4/2025	Removed requirement for smoking cessation counseling, removed exclusion criteria, removed additional documentation for confirming diagnosis of TED (now just require a CAS score $\geq$ 4)
9/2025	Thyroid status (euthyroid or mild hyper/hypothyroidism) updated to require documentation within the past 12 months
8/2026	Added Lumvoa Revised Tepezza criteria to align closer with Lumvoa

MEDICAL POLICY

Medical Policy Title	**Testing for the Use of Biologic Therapeutics for the Treatment of Inflammatory Disorders**
Policy Number	**2.02.47**
Current Effective Date	**November 1, 2026**
Next Review Date	**November 2027**

Our medical policies are based on the assessment of evidence based, peer-reviewed literature, and professional guidelines. Eligibility for reimbursement is based upon the benefits set forth in the member's subscriber contract. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Measurement of serum and/or antibody levels for biologic therapies (e.g., Infliximab, Adalimumab, Vedolizumab, Ustekinumab) pre- or post-treatment in patients with inflammatory disorders, are considered **investigational**, and include but are not limited to **ANY** of the following tests:

   A. Procise ADL;

   B. Procise IFX;

   C. PredictrPK IFX;

   D. ADALX (Adalimumab Quantitative with Reflex to Antibody, Serum) test;

   E. Anser ADA test;

   F. Anser IFX test;

   G. Anser UST test;

   H. Anser VDZ test.

II. Testing used to predict the likelihood of response or non-response to biologic therapies (e.g., PrismRA), either alone or as a combination test are considered **investigational**.

DESCRIPTION

Biological therapeutics are defined by the World Health Organization (WHO) as a class of medicines that are grown and then purified from large scale cell cultures of bacteria or yeast, plant, or animal cells. They are used in vaccines, growth factors, immune modulators, or monoclonal antibodies.

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

- Examples of biological therapeutics are infliximab (Remicade) (IFX), adalimumab (Humira)(ADA), vedolizumab (Entyvio) (VDZ), and ustekinumab (Stelara) (UST), etanercept (Enbrel), certolizumab (Cimzia).
- Infliximab, adalimumab, etanercept, certolizumab are anti-tumor necrosis factor-α (anti-TNF-α) therapies. These therapies are effective when there is insufficient control of disease with conventional treatment in patients with inflammatory disorders, such bowel disease (IBD), ulcerative colitis, Crohn's disease, rheumatoid arthritis (RA), psoriatic arthritis, and ankylosing spondylitis.

Up to 30% of patients may not initially respond to anti-TNF-α therapy, and among those who do, up to 60% may lose responsiveness over time. This diminished or absent response is thought to be linked to the development of antibodies against anti-TNF agents, particularly Infliximab. These antibodies, known as Anti-Infliximab Antibodies (ATI) or human antichimeric antibodies (HACAs), can form as early as after the first dose and persist for years, potentially reducing drug concentration and efficacy due to accelerated clearance. Their presence is also associated with adverse reactions, including acute infusion and delayed hypersensitivity responses. To manage nonresponse, clinicians may adjust the dose or interval, switch to another anti-TNF drug, or opt for a different class of medication. Because loss of response can lead to relapse, reduced quality of life, and increased healthcare costs, monitoring serum drug and antibody levels has been suggested as part of anti-TNF therapy regimens.

Detection of drug and antidrug antibodies is commonly performed using ELISA, radioimmunoassay (RIA), and homogenous mobility shift assay (HMSA), each with its own limitations. ELISA is restricted to measuring antidrug antibodies only when drug levels are undetectable, while RIA involves complex procedures, extended incubation times, and safety concerns due to radioactive materials. HMSA offers the advantage of detecting antibodies even in the presence of the drug in serum. However, technical inconsistencies across these methods hinder reliable interstudy comparisons, and standardized threshold values for Infliximab or adalimumab antibodies have yet to be established for each assay type.

Prometheus Laboratories Inc. offers non-radiolabeled, fluid-phase homogenous mobility shift assay (HMSA) tests called Anser IFX for infliximab, Anser ADA for adalimumab, Anser VDZ for vedolizumab, and Anser UST for ustekinumab. The four tests are not enzyme-linked immunosorbent assay (ELISA)-based; however, each can measure anti-drug antibodies in the presence of detectable drug levels, improving on a major limitation of the ELISA method. The tests measure serum drug concentrations and anti-drug antibodies.

The PrismRA (Scipher Medicine laboratory) test predicts the likelihood of non-response to TNFi therapies. The test analyzes 23 biological features, including RNA expression data, demographic variables, and disease-associated clinical metrics, which are discriminatory between the molecular signatures of those who respond or do not respond adequately to TNFi therapies.

SUPPORTIVE LITERATURE

Bronsky et al (2025) conducted a prospective single-center observational study that evaluated the usefulness of therapeutic drug monitoring (TDM) for ustekinumab (USTE) and vedolizumab (VEDO) in pediatric inflammatory bowel disease (pIBD) patients. This study involved 87 children with Crohn's disease, ulcerative colitis, or unclassified IBD, analyzing 641 drug observations. The primary goal was to assess the relationship between serum trough levels (TLs) and disease activity, measured by fecal calprotectin (F-CPT). The study found that USTE trough levels were not significantly associated with disease activity, as measured by F-CPT, suggesting limited value of TDM for USTE in pediatric IBD. In contrast, VEDO trough levels showed a negative association with F-CPT levels, indicating a potential role for TDM in guiding VEDO therapy. However, the ability of VEDO trough levels to predict remission (F-CPT < 250 µg/g) was poor, with an optimal threshold of 15.1 µg/mL yielding high sensitivity (0.82) but low specificity (0.32), and an area under the curve (AUC) of only 0.56. Other factors such as treatment phase, drug intensification, undetectable TLs, and IBD type were not significantly linked to disease activity. Mild anti-drug antibodies were found in a few cases (5 USTE, 16 VEDO) but had no clinical impact. Overall, TDM may be helpful for VEDO but not for USTE, and clinically useful dosing thresholds remain difficult to establish.

Nguyen et al (2022) conducted a systematic review and metanalysis of RCTs comparing TDM with conventional management in patients with IBD. Proactive TDM has been proposed to improve outcomes in patients with IBD being treated with TNFα antagonists. The study identified RCTs in patients with IBD treated with TNFα antagonists comparing proactive TDM through routine assessments of trough concentration, regardless of trough concentrations, with conventional management where dose adjustments were driven by clinical assessments. In the nine RCTs that were used for the metanalysis, it was found that there was no significant difference in the failing to maintain clinical remission in patients who underwent proactive TDM. The proactive TDM arm was more likely to undergo dose escalation, however there was no difference found in the risk of developing antidrug antibodies or other serious adverse events. In conclusion it was found that in patients with IBD treated with TNFα antagonists, regardless of disease activity, routine TDM to target biologic concentration to specific thresholds did not show clinical benefit. The RCTs focused on adults and optimization of TNFα antagonist during the maintenance phase, further studies would be needed to assess induction phase of drug use, or if individuals with more severe phenotype may benefit from routine proactive TDM.

Syversen et al (2021) conducted a randomized, parallel-group, open-label clinical trial for 411 adults with rheumatoid arthritis, spondyloarthritis, psoriatic arthritis, ulcerative colitis, Crohn's disease, or psoriasis initiating infliximab therapy. The researchers aimed to assess whether TDM during initiation of infliximab therapy improves the efficiency of treatment compared to the standard without TDM. Participants were randomized 1:1 (198 in the TDM group and 200 in the standard therapy group) Clinical readmission at 30 weeks was achieved in 50.5% for TDM and 53% in the standard groups. Adverse events were reported in 68% in TDM and 70% in standard groups. The finding reported do not support routine use of TDM during infliximab induction for improving disease remission rates. It was suggested that further studies should be completed to determine if TDM is associated with fewer infusion reactions. Limitations included lack of double blinding, open label, and discrepancies

amongst assays for infliximab and antidrug antibodies, and individual patient responses to treatment.

Steenholdt et al (2014) published a post hoc comparison of different ATI assays. Blood samples were collected from 66 of 69 patients enrolled in an RCT (discussed next) that assessed algorithmic treatment for CD relapse during infliximab therapy. Samples were analyzed by three binding assays: RIA, ELISA, and HMSA; and by a reporter gene assay, a functional cell-based technique. ATI were detected in 18 patients (27%) by radioimmunoassay, six patients (9%) by ELISA, and 22 patients (33%) by HMSA. The reporter gene assay reported anti-infliximab activity, most likely due to ATI, in seven patients (11%). As observed by the authors, this suggests that ATI detected by RIA and HMSA are not necessarily functionally active. Five patients (8%) were ATI-positive, and 43 patients (65%) were ATI-negative by all four assays. Correlations were statistically significant ($p<0.001$) in all pairwise comparisons (Pearson *r*, 0.77-0.96). However, statistical agreement between assays could not be estimated accurately (e.g., using the intraclass correlation coefficient) because different assays reported values on different arbitrary scales. Regardless of assay used, most patients (74%-88%) had therapeutic serum infliximab levels and undetectable ATI, suggesting nonpharmacologic reasons for relapse or for symptoms mimicking relapse.

Wang et al (2013) developed and validated a non-radiolabeled HMSA to measure antibodies-to-adalimumab (ATA) and adalimumab levels in serum samples. Analytic validation of performance characteristics (calibration standards, assay limits, intra- and inter-assay precision, linearity of dilution, substance interference) was performed for both the ATA- and adalimumab HMSA. Because the elimination half-life of adalimumab (10-20 days) overlaps the dosing interval (every two weeks), ATA-positive sera to provide calibration standards were difficult to collect from human patients. (The drug-free interval for antibody formation is small.) Therefore, anti-sera from rabbits immunized with adalimumab were pooled to form calibration standards. Serial dilutions of these ATA calibration standards then generated a standard curve against which test samples were compared. Over the course of 29 experimental runs, intra-assay precision and accuracy for the adalimumab-HMSA (as indicated by the CV) was < 20% and < 3%, respectively; inter-assay (run-to-run, analyst-to-analyst, and instrument-to-instrument) precision and accuracy were less than 12% and less than 22%, respectively. For the ATA HMSA, CVs for intra-assay precision and accuracy were less than 3% and less than 13%, respectively; CVs for inter-assay precision and accuracy were less than 9% and less than 18%, respectively. ELISA could not be used as a standard comparator, due to competition from the circulating drug. Analysis of 100 serum samples from patients who were losing response to adalimumab showed that 44% were above the cut point for ATA (0.55 U/mL), and 26% were below the cut point for serum adalimumab level. In samples below the adalimumab cut point (0.68 µg/mL), 68% were ATA-positive; in samples with adalimumab levels greater than 20 µg/mL, 18% were ATA-positive.

Lee et al (2012) conducted a meta-analysis of patients with IBD receiving infliximab to determine the prevalence of ATI, the effect of ATI on the prevalence of infusion reactions, and the effect of ATI on disease remission rates. Databases were searched through October 2011, and 18 studies involving 326 patients were included. The studies included nine randomized, controlled trials (RCTs), five cohort studies, and four retrospective cohort studies. The prevalence of ATI was 45.8% when

episodic infusions of infliximab were given and 12.4% when maintenance infliximab was given. The rates of infusion reactions were significantly higher in patients with ATI (relative risk [RR], 2.07; 95% confidence interval [CI], 1.61 to 2.67). Immunosuppressants resulted in a 50% reduction in the risk of developing ATI ($p<0.001$). Patients with ATI were less likely to be in clinical remission, but this was not statistically significant (RR=0.90; 95% CI, 0.79 to 1.02; p=0.10). The meta-analysis concluded that patients who test positive for ATI are at an increased risk of infusion reactions but have similar rates of remission compared with patients who test negative for ATI.

The clinical utility of vedolizumab trough levels (VTLs) in IBD is not well-defined. The data to support the routine use of therapeutic drug-monitoring during maintenance therapy are lacking. Further studies to determine the role of therapeutic drug-monitoring of vedolizumab are needed.

PROFESSIONAL GUIDELINE(S)

American College of Gastroenterology 2019 Clinical Guidelines for Ulcerative Colitis (UC) in Adults, states:

- "In patients with moderately to severely active UC who are responders to anti-TNF therapy and now losing response, we suggest measuring serum drug levels and antibodies (if there is not a therapeutic level) to assess the reason for loss of response (conditional recommendation, very low quality of evidence)".

National Institute for the Health and Care Excellence (NICE) 2022 Guidelines for ProciseDx Point-of-Care Platform for Inflammatory Bowel Disease states:

- "Further research needs to evaluate the use of ProciseDx in clinical care for diagnosing and monitoring IBD, including its effect on clinical decision making and dosing resource use and patient outcomes."

REGULATORY STATUS

ProciseDx has been U.S. Food and Drug Administration cleared for therapeutic Drug Monitoring (TDM) for Infliximab and Adalimumab.

Anser tests by Prometheus Laboratories have not been cleared or approved by the US FDA.

Infliximab, adalimumab, vedolizumab, and ustekinumab are biologic therapeutics that have received approval by the U.S. Food and Drug Administration (FDA).

CENTERS FOR MEDICARE AND MEDICAID SERVICES (CMS)

There is currently no National Coverage Determination (NCD) or Local Coverage Determination (LCD) for Measurement of Serum Antibodies to Infliximab and Adalimumab.

PRODUCT DISCLAIMER

- Services are contract dependent; if a product does not cover a service, medical policy criteria do not apply.
- If a commercial product (including an Essential Plan or Child Health Plus product) covers a specific service, medical policy criteria apply to the benefit.
- If a Medicaid product covers a specific service, and there are no New York State Medicaid guidelines (eMedNY) criteria, medical policy criteria apply to the benefit.
- If a Medicare product covers a specific service, and there is no national or local Medicare coverage decision for the service, medical policy criteria apply to the benefit.

Disclaimer Notice

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgment when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

Background

The Centers for Disease Control and Prevention (CDC) estimates that 25 million Americans, including five million children, have asthma. Patients with severe asthma represent fewer than five to ten percent of all individuals with asthma. In addition to being treated with inhaled corticosteroids (ICS) and long-acting beta agonist (LABA) therapy, these patients are often treated with oral corticosteroids (OCS).

Tezspire (tezepelumab) is a thymic stromal lymphopoietin (TSLP) blocker, human monoclonal antibody (IgG2λ), indicated for the add-on maintenance treatment of adult and pediatric patients aged 12 years and older with severe asthma. TSLP is believed to play important roles in type 2 immunity but, also in other inflammatory pathways.

The Global Initiative for Asthma (GINA) guidelines recommend treatment by a specialist when asthma cannot be controlled by standard inhaler treatment with confirmed adherence and proper inhaler technique. With a confirmed diagnosis of severe asthma, patients should be evaluated for type 2 inflammation. Patients without type 2 inflammation may be appropriate for biologic therapy including Tezspire. Of note, the GINA guidelines do specifically call out that there is insufficient evidence for the use of Tezspire in patients on maintenance oral corticosteroids. In patients with type 2 inflammation, Tezspire is noted in guidelines to be appropriate for patients with exacerbations in the last year. Patients with higher blood eosinophils and higher FeNO are predicted to have better outcomes with Tezspire. It is recommended that type 2 targeted biologics are trialed for a 4-month time period. If within these 4 months the patient does not demonstrate a response, they should be switched to a different agent.

Summary

Effective Date of Policy:	6/15/2026
Indications	Add-on maintenance treatment of adult and pediatric patients aged 12 years and older with severe asthma
ICD10 Diagnosis Codes	J45 (subcodes), J32 and 33 subcodes
HCPCS	J2356
Availability	*210 mg/1.91 mL (110 mg/mL) solution in a single-dose glass vial* *210 mg/1.91 mL (110 mg/mL) solution in a single-dose pre-filled syringe*
Duration	Initial: six months Continuation: two years

Required Criteria for Initial Approval

All of the following conditions for the requested indication must be met in order to approve therapy:

Specific Indication	Criteria
Indication **Add-on maintenance treatment of adult and pediatric patients aged 12 years and older with severe asthma** (FDA approval) ICD10: J45	1. Therapy is being requested by a pulmonologist or allergist/immunologist **AND** 2. The member is at least 12 years of age or older **AND** 3. The member must have severe asthma **AND** 4. The member must be a non-smoker defined as someone who has not smoked in the preceding six months **AND** 5. The member must have well-documented use of high-dose inhaled corticosteroids (ICS) (see Tables 1-3 in considerations section) for at least 3 months, be compliant with existing therapy, and have followed GINA guidelines for asthma treatment including an adequate trial of a high-dose inhaled steroid in combination with a long-acting beta agonist a. Compliance will be assessed based on pharmacy refill history. If the patient does not have pharmacy benefits through this health plan, a recent pharmacy profile will be requested. Progress notes documenting usage of sample medication may also be requested. b. If there is a contraindication to use of a long-acting beta agonist, then an alternative controller drug may be used in combination with a high-dose inhaled steroid such as a leukotriene inhibitor or long-acting muscarinic antagonist.

	c. Patient must have documentation of inadequate control despite optimal therapy (above) for a period of at least 3 months **AND** 6. Tezspire must be used in combination with existing asthma therapy (as defined above). a. Monotherapy will not be authorized as this agent is only FDA-approved as add-on maintenance treatment **AND** 7. The patient must have eosinophils < 150 cells per microliter (the measurement must have been taken within the last 6 weeks) AND the patient must NOT be oral corticosteroid dependent (OCS; OCS-dependence is defined as reliance on daily, maintenance oral prednisone, methylprednisolone, etc. [OCS-dependence should be supported by clinical progress notes and/or pharmacy claims]) **AND** 8. The member must have experienced 2 or more asthma exacerbations despite therapy, within the preceding 12 months that required medical attention (defined as non-routine doctor visits, urgent care, emergency room visits or documented need for acute systemic steroids). 9. Initial approval will be for 6 months. Subsequent recertifications will be for 2 years and will require an objective assessment of response from the provider (reductions in hospitalizations, ER visits, and rescue medication use) as well as compliance history with the inhaled corticosteroid and controller medication. Recertification will not be granted if the patient starts or re-starts smoking. See recertification statement and additional approval time-period table for medical benefit in policy guidelines section of this policy. 10. Dosing: 210 mg subcutaneously once every 4 weeks
Chronic Rhinosinusitis with Nasal Polyps (FDA approval) ICD10: J32 and J33	1. Must be prescribed by or in consultation by an Allergist/Immunologist, or Otolaryngologist **AND** 2. Must have a diagnosis of chronic rhinosinusitis with nasal polyps (CRSwNP) a. Chronic is defined as having lasted for at least 12 weeks **AND** b. Must currently have nasal polyposis, confirmed by evidence (such as direct examination, nasal endoscopy, imaging studies such as a sinus CT scan) 3. Must be ≥ 12 years of age **AND** 4. Must have had either: **a.** Prior nasal surgery **OR** **b.** Prior treatment with a course of systemic corticosteroids 5. Step therapy applies – Step therapy (a **AND** b) applies to New Starts for all lines of business, **including** Medicare Part B: a. Must have documented inadequate response despite at least 3 months of compliant use of mometasone nasal spray at a dose of 2 sprays in each nostril twice daily (compliance will be verified through pharmacy claims history. Note: each inhaler =17g = 120 sprays, therefore claims should reflect **34 g/30 days** for the required dosing) **AND** b. Must have documented inadequate response despite at least 3 months of compliant use of Xhance nasal spray at a dose of 2 sprays in each nostril twice daily (compliance will be verified through pharmacy claims history. Note: each inhaler =16ml = 120 sprays, therefore claims should reflect **32 ml/30 days** for the required dosing) **AND** 6. Must have had serious side effects or drug failure of Dupixent unless there is a medical reason why Dupixent cannot be used 7. Must be used in combination with an intranasal corticosteroid a. Tezspire as monotherapy for this indication will not be authorized as both agents are only FDA approved as an add-on maintenance treatment 8. Approved dosing: Tezspire 210mg once every 4 weeks 9. Initial approval will be granted for **6** months. All recertifications will be for 2 years and will require documentation of continued use of an intranasal corticosteroid and clinical benefit from Tezspire use (e.g., reduced nasal polyp size, improved nasal congestion, reduced sinus opacification, decreased sino-nasal symptoms, improved sense of smell) 10. Tezspire will not be approved for use in combination with Dupixent, Nucala or Xolair for Chronic Rhinosinusitis with Nasal Polyps

Exclusion Criteria

- Tezspire will not be approved as monotherapy for asthma
- Tezspire will not be approved to be used in combination with other biologic therapies for the treatment of asthma or nasal polyps.

- For any diagnosis, if Tezspire therapy is initiated with samples and the member does not meet our criteria for coverage (as outlined above) before the start of Tezspire therapy, upon completion of the samples, coverage of Tezspire will not be granted.

Considerations

- Prior authorization is obtained through the CDPHP pharmacy department.

Table 1:

Estimated comparative daily doses for inhaled glucocorticoids in adolescents ≥12 years and adults

Drug	Low dose (total daily dose)	Medium dose (total daily dose)	High dose (total daily dose)*
Beclomethasone HFA (Qvar RediHaler product available in United States) Administer as 2 divided doses	80 to 160 mcg	>160 to 320 mcg	>320 to 640 mcg
40 mcg per actuation	2 or 4 inhalations	¶	¶
80 mcg per actuation	2 inhalations	4 inhalations	6 or 8 inhalations
Beclomethasone HFAΔ (Qvar product available in Canada, Europe, and elsewhere) Administer as 2 divided doses	100 to 200 mcg	>200 to 400 mcg	>400 to 800 mcg
50 mcg per actuation	2 to 4 inhalations	¶	¶
100 mcg per actuation	2 inhalations	4 inhalations	6 or 8 inhalations
Budesonide DPI (Pulmicort Flexhaler product available in United States) Administer as 2 divided doses	180 to 360 mcg	>360 to 720 mcg	>720 to 1440 mcg
90 mcg per actuation	2 or 4 inhalations	¶	¶
180 mcg per actuation	2 inhalations	4 inhalations	6 or 8 inhalations
Budesonide DPIΔ (Pulmicort Turbuhaler or Turbohaler product available in Canada, Europe, and elsewhere) Administer low doses (ie, ≤400 mcg/day) once daily; administer higher doses (ie, >400 mcg/day) as 2 to 4 divided doses	200 to 400 mcg	>400 to 800 mcg	>800 to 2400 mcg
100 mcg per actuation	2 to 4 inhalations	¶	¶
200 mcg per actuation	1 to 2 inhalations	3 to 4 inhalations	¶
400 mcg per actuation	1 inhalation	2 inhalations	3 to 6 inhalations
Ciclesonide HFA (Alvesco product available in United States, Europe, and elsewhere) United States: Administer as 2 divided doses Australia, Europe, and elsewhere: Administer lower doses (ie, 160 to 320 mcg/day) once daily; administer 640 mcg dose as 2 divided doses	160 mcg	320 mcg	640 mcg
80 mcg per actuation	2 inhalations	4 inhalations	¶
160 mcg per actuation	◇	2 inhalations	4 inhalations
Ciclesonide HFAΔ (Alvesco product available in Canada) Administer lower doses (eg, 100 to 400 mcg) once daily; administer 800 mcg dose as 2 divided doses	100 to 200 mcg	>200 to 400 mcg	>400 to 800 mcg
100 mcg per actuation	1 to 2 inhalations	3 to 4 inhalations	¶
200 mcg per acutation	1 inhalation	2 inhalations	3 to 4 inhalations

Fluticasone propionate HFA (Flovent HFA product available in United States) Administer as 2 divided doses	176 to 220 mcg	>220 to 440 mcg	>440 to 1760 mcg
44 mcg per actuation	4 inhalations	¶	¶
110 mcg per actuation	2 inhalations	4 inhalations	¶
220 mcg per actuation	◇	2 inhalations	4 to 8 inhalations
Fluticasone propionate HFAΔ (Flovent HFA product available in Canada; Flixotide Evohaler product available in Europe and elsewhere) Administer as 2 divided doses	100 to 250 mcg	>250 to 500 mcg	>500 to 2000 mcg
50 mcg per actuation	2 to 4 inhalations	¶	¶
125 mcg per actuation	2 inhalations	4 inhalations	¶
250 mcg per actuation	◇	2 inhalations	4 to 8 inhalations
Fluticasone propionate DPI (Flovent Diskus product available in United States and Canada; Flixotide Accuhaler product available in Europe and elsewhere) Administer as 2 divided doses	100 to 250 mcg	>250 to 500 mcg	>500 to 2000 mcg
50 mcg per actuation	2 to 4 inhalations	¶	¶
100 mcg per actuation	2 inhalations	4 inhalations	¶
250 mcg per actuation	◇	2 inhalations	4 to 8 inhalations
500 mcg per actuation (strength not available in United States)	◇	◇	2 or 4 inhalations
Fluticasone propionate DPI (Armonair Digihaler product available in United States; Aermony Respiclick product available in Canada) Administer as 2 divided doses	110 mcg	226 mcg	464 mcg
55 mcg per actuation	2 inhalations	¶	¶
113 mcg per actuation	◇	2 inhalations	¶
232 mcg per actuation	◇	◇	2 inhalations
Fluticasone furoate DPI (Arnuity Ellipta product available in United States, Canada, Australia, and elsewhere, but not available in Europe or UK) Administer once daily **NOTE:** Inhaled fluticasone furoate has a greater anti-inflammatory potency per microgram than fluticasone propionate inhalers. Thus, fluticasone furoate is administered at a lower daily dose and used only once daily.	50 mcg (by use of pediatric DPI, which is off-label in adolescents and adults)	100 mcg	200 mcg
50 mcg per actuation	1 inhalation	¶	¶
100 mcg per actuation	◇	1 inhalation	2 inhalations
200 mcg per actuation	◇	◇	1 inhalation
Mometasone DPI (Asmanex Twisthaler product available in United States) May administer lower doses (ie, 220 to 440 mcg/day) once daily; administer 880 mcg dose as 2 divided doses	220 mcg	>220 to 440 mcg	>440 to 880 mcg
110 mcg per actuation	2 inhalations	¶	¶
220 mcg per actuation	1 inhalation	2 inhalations	4 inhalations

Mometasone DPI (Asmanex Twisthaler product available in United States) May administer lower doses (ie, 220 to 440 mcg/day) once daily; administer 880 mcg dose as 2 divided doses	220 mcg	>220 to 440 mcg	>440 to 880 mcg
110 mcg per actuation	2 inhalations	¶	¶
220 mcg per actuation	1 inhalation	2 inhalations	4 inhalations
Mometasone HFA (Asmanex HFA product available in United States) Administer as 2 divided doses	200 mcg	>200 to 400 mcg	>400 to 800 mcg
100 mcg per actuation	2 inhalations	4 inhalations	¶
200 mcg per actuation	◇	2 inhalations	4 inhalations
Mometasone DPIΔ (Asmanex Twisthaler product available in Canada, Europe, and elsewhere) May administer lower doses (ie, 200 to 400 mcg/day) once daily; administer 800 mcg dose as 2 divided doses	200 mcg	>200 to 400 mcg	>400 to 800 mcg
200 mcg per actuation	1 inhalation	2 inhalations	¶
400 mcg per actuation	◇	1 inhalation	2 inhalations

- **The most important determinant of appropriate dosing is the clinician's judgment of the patient's response to therapy.** The clinician must monitor the patient's response on several clinical parameters and adjust the dose accordingly. The stepwise approach to therapy emphasizes that once control of asthma is achieved, the dose of medication should be carefully titrated to the minimum dose required to maintain control, thus reducing the potential for adverse effects.
- Suggested total daily doses for low, medium, and high dose inhaled glucocorticoid regimens are based on daily doses recommended by Global Initiative for Asthma (GINA), National Asthma Education and Prevention Program (NAEPP), and/or product labeling[1-5]. This is not a table of equivalence.
- Depending on the specific product, total daily doses are administered once or divided and given twice daily. Refer to local product information or a clinical drug reference (eg Lexicomp).
- Some doses are outside the approved product information recommendations.

DPI: dry powder inhaler; HFA: hydrofluoroalkane propellant metered dose inhaler.

* Evidence for additional improvement with dose increases >1000 mcg/day is limited.

¶ Select alternate preparation with higher mcg/actuation to improve convenience.

Δ Products shaded in light gray color are not available in the United States but are available widely elsewhere.

◇ Select preparation with fewer mcg/actuation.

Table 2:

Usual doses of combined inhaled glucocorticoids and bronchodilators

Medication	Low dose	Medium dose	High dose
ICS-SABA combination			
Budesonide-albuterol HFA (Brand name: Airsupra)*			
NOTE: Not used for maintenance therapy.			
Acute symptom relief: Budesonide-albuterol (80 mcg/90 mcg) 2 inhalations as needed (usual maximum: 12 inhalations/day).			
ICS-LABA combinations			
Beclomethasone [beclometasone]-formoterol DPI or HFA (Not available in United States or Canada, but available elsewhere [sample brand names: Formodual, Fostair, Foster])¶Δ			
100 mcg/6 mcg	1 inhalation twice a day	2 inhalations twice a day	
200 mcg/6 mcg			2 inhalations twice a day
Budesonide-formoterol HFA (Brand name: Symbicort)¶			
80 mcg/4.5 mcg	2 inhalations twice a day		
160 mcg/4.5 mcg		2 inhalations twice a day	
Fluticasone furoate-vilanterol DPI (Brand name: Breo Ellipta)Δ			
NOTE: Inhaled fluticasone furoate has a greater anti-inflammatory potency per microgram than fluticasone propionate inhalers. Thus, fluticasone furoate is administered at a lower daily dose and used only **once** daily.			
50 mcg/25 mcg◇	1 inhalation once daily		
100 mcg/25 mcg		1 inhalation once daily	
200 mcg/25 mcg			1 inhalation once daily
Fluticasone propionate-formoterol MDI (Not available in United States or Canada, but available elsewhere [sample brand name: Flutiform])			
50 mcg/5 mcg	2 inhalations twice daily		
125 mcg/5 mcg		2 inhalations twice daily	
250 mcg/10 mcg			2 inhalations twice daily
Fluticasone propionate-salmeterol DPI (Brand names: Advair Diskus, Wixela Inhub)Δ			
100 mcg/50 mcg	1 inhalation twice a day		
250 mcg/50 mcg		1 inhalation twice a day	
500 mcg/50 mcg			1 inhalation twice a day
Fluticasone propionate-salmeterol HFA (Brand name: Advair HFA)			
45 mcg/21 mcg	2 inhalations twice a day		
115 mcg/21 mcg		2 inhalations twice a day	
230 mcg/21 mcg			2 inhalations twice a day
Fluticasone propionate-salmeterol DPI (Brand names: AirDuo RespiClick, AirDuo Digihaler)Δ§			
55 mcg/14 mcg	1 inhalation twice a day		
113 mcg/14 mcg	1 inhalation twice a day	1 inhalation twice a day	
232 mcg/14 mcg			1 inhalation twice a day
Mometasone-formoterol HFA (Brand name: Dulera)			
100 mcg/5 mcg		2 inhalations twice a day	
200 mcg/5 mcg			2 inhalations twice a day
Mometasone-indacaterol DPI (Brand name: Atectura Breezhaler; available in Canada)Δ			
80 mcg/150 mcg	1 inhalation (capsule) once a day		
160 mcg/150 mcg		1 inhalation (capsule) once a day	
320 mcg/150 mcg			1 inhalation (capsule) once a day
ICS-LAMA-LABA combinations¥			
Fluticasone furoate-umeclidinium-vilanterol DPI (Brand name: Trelegy Ellipta)Δ			
100 mcg/62.5 mcg/25 mcg		1 inhalation once daily	
200 mcg/62.5 mcg/25 mcg			1 inhalation once daily
Mometasone-glycopyrrolate (glycopyrronium)-indacaterol DPI (Brand name: Enerzair Breezhaler; available in Canada)*Δ			
160 mcg/50 mcg/150 mcg			1 inhalation (capsule) once a day

Do not exceed the maximum number of inhalations/puffs per day listed in the table due to the risk of toxicity from an excess dose of long-acting beta-agonist (ie, salmeterol, formoterol, or vilanterol). Brand names and dose per puff or per inhalation of commercially available fixed dose combinations are according to United States prescribing information, unless otherwise noted. Consult local product information before use.

ICS: inhaled glucocorticoid (inhaled corticosteroid); SABA: short-acting beta-agonist; LABA: long-acting beta-agonist; LAMA: long-acting muscarinic antagonist; HFA: metered dose inhaler with hydrofluoroalkane propellant; DPI: dry powder inhaler; SMI: soft mist inhaler.

* Not approved for use in patients <18 years old.

¶ When using ICS-formoterol as reliever, use one to two inhalations as needed. Maximum daily dose of maintenance and rescue is 12 inhalations.

Δ DPI contains lactose which may have small amounts of milk protein.

◇ Fluticasone furoate-vilanterol 50 mcg/25 mcg DPI is approved for use in patients 5 to 11 years old; use in adolescents and adults is off-label.

§ In AirDuo inhalers, the daily dose of salmeterol is approximately one-fourth of the dose in Advair, and the daily dose of fluticasone is approximately one-half that of the comparable low-, medium-, and high-dose strengths of Advair.

¥ Alternatively, tiotropium SMI (Brand name: Spiriva Respimat) can be used with an ICS or ICS-LABA inhaler. The dose in asthma is two inhalations (1.25 mcg/inhalation) once daily.

Ciclesonide HFAΔ 80 or 160 mcg/puff	NA	80 mcg/puff - 1 to 2 puffs once daily	NA	80 mcg/puff - 3 to 4 puffs once daily	NA	80 mcg/puff - 5 to 6 puffs once daily or as 2 divided doses 160 mcg/puff - 3 puffs once daily or as 2 divided doses
Fluticasone HFA◇ 44, 110, or 220 mcg/puff	44 mcg/puff - 2 puffs twice per day◇	44 mcg/puff - 1 to 2 puffs twice per day	44 mcg/puff - 2 to 4 puffs twice per day 110 mcg/puff - 1 puff in AM and 2 puffs in PM	44 mcg/puff - 2 to 4 puffs twice per day 110 mcg/puff - 1 puff in AM and 2 puffs in PM	110 mcg/puff - 2 puffs twice per day 220 mcg/puff - 1 puff twice per day	110 mcg/puff - 2 puffs twice per day 220 mcg/puff - 1 puff twice per day
Fluticasone DPI (breath activated)§ 50, 100, or 250 mcg/inhalation	NA	50 mcg/inhalation - 1 to 2 inhalations twice per day	NA	50 mcg/inhalation - 3 to 4 inhalations twice per day 100 mcg/inhalation - 1 inhalation in AM and 2 inhalations in PM to 2 inhalations twice per day	NA	100 mcg/inhalation - 2 inhalations in AM and 3 inhalations in PM 250 mcg/inhalation - 1 inhalation twice per day
Mometasone aerosol DPI (breath activated)* 110 or 220 mcg/inhalation	NA	110 mcg/inhalation - 1 inhalation once daily	NA	110 mcg/inhalation - 2 to 3 inhalations once daily	NA	110 mcg/inhalation - 4 inhalations once daily or 2 inhalations twice per day 220 mcg/inhalation - 2 inhalations once daily or 1 inhalation twice per day
Mometasone HFA MDI 50, 100, or 200 mcg/puff	NA	50 mcg/puff - 1 puff once or twice per day	NA	50 mcg/puff - 2 to 3 puffs twice per day 100 mcg/puff - 1 puff twice per day	NA	100 mcg/puff - 2 puffs twice per day 200 mcg/puff - 1 inhalation twice per day

Some doses may be outside approved package labeling, especially in the high-dose range. Doses shown and strengths (ie, mcg per puff or inhalation) are based upon product descriptions approved in the United States, which may differ from how strengths are described for products available in other countries. Consult local product information before use.

HFA: hydrofluoroalkane; NA: not approved and no data available for this age group; DPI: dry-powder inhaler; AM: in morning; PM: in evening; US FDA: US Food and Drug Administration; MDI: metered-dose inhaler.

* Contains milk protein.

¶ Budesonide suspension is compatible with albuterol, ipratropium, and levalbuterol nebulizer solutions in the same nebulizer. Use only jet nebulizers as ultrasonic nebulizers are ineffective for suspensions.

Δ Ciclesonide is not approved by the US FDA for use in children under 12. It is approved for use in children 6 years of age and older in Canada, some European countries, and elsewhere.

◇ For fluticasone HFA, the low dose for children <4 years is higher than for children 5 to 11 years of age due to lower dose delivered with facemask and data on efficacy in young children.

§ Contains lactose.

GOVERNMENT PROGRAMS

CHILD HEALTH PLUS:	Subject to all terms and conditions noted in above application.
MEDICARE CHOICES:	Subject to all terms and conditions noted in above application if administered under the medical benefit
SELECT/HARP PLAN:	Effective April 1, 2023, the pharmacy benefit for Medicaid is administered by NYRx, the Medicaid Pharmacy Program

CDPHP Pharmacy Services 6/15/2026

New: 4/2022

Date	Notes
4/2023	Reviewed with no changes
4/2024	Revised: • Background updated to reflect current guidelines • Removed exclusion criteria of eosinophilic or allergic asthma diagnosis • Changed the criteria related to smoking status from "The enrollee must not use tobacco products or have had a greater than 10 pack-year past history of smoking" to "The enrollee must be a non-smoker defined as someone who has not smoked in the preceding 6 months"
4/2025	Revised. Added allergist/immunologist as acceptable prescribers
6/2025	Removed requirement that the member must have a specific eosinophil count
12/2025	Added indication for Chronic Rhinosinusitis with Nasal Polyps
6/2026	Added corticosteroid tables to considerations section Updated asthma criteria wording

MEDICAL POLICY

Medical Policy Title	**Therapies (Speech, Physical, and Occupational)**
Policy Number	**8.01.24**
Current Effective Date	**January 1, 2027**
Next Review Date	**November 2027**

Our medical policies are based on the assessment of evidence based, peer-reviewed literature, and professional guidelines. Eligibility for reimbursement is based upon the benefits set forth in the member's subscriber contract. (Link to Product Disclaimer)

POLICY STATEMENT(S)

Table of Contents

Initial Therapy Requests
Continuation of Services
Speech Therapy
- Dysphagia and Feeding Difficulties
- Vocal Cord Dysfunction
- Voice Therapy

Physical and Occupational Therapy
- Non-Skilled/Not Medically Necessary Services
- Investigational Services

Individualized Education Program (IEP)

Initial Therapy Requests

I. Restorative or habilitative physical therapy (PT), occupational therapy (OT) or speech therapy (ST) are considered **medically appropriate** with **ANY** of the following indications when determined by standardized assessments:
   A. Functional physical impairment due to disease;
   B. Trauma/injury;
   C. Previous therapeutic processes (e.g., traumatic brain injury, cardiovascular accident/stroke);
   D. Prior therapeutic intervention(s);
   E. Children exhibiting at least a moderate to severe delay or disability as determined by standardized assessments, resulting from disease, trauma, congenital anomaly, or developmental delay;
      1. A moderate to severe deficit is generally defined as (Refer to Policy Guideline):
         a. A score at least 1.5 standard deviations below the mean (i.e., a standard score of 77 or below for most standardized tests that have an average score of 100 with a

standard deviation of 15). (Standardized Speech Tests)

2. Cross-disciplinary and age equivalency scores may be considered, as well as percentage scores, and standard deviation when determining the severity of the impairment.

II. In determining the **medical appropriateness** of PT, OT or ST services, consideration will be given to individuals based on **BOTH** of the following criteria:

A. The degree of limitation/deficit the impairment imposes on the individual; **and**

B. Deficit(s) are expected to improve over a short period of time (generally up to two (2) months) with treatment.

Continuation of Services

III. Continuation of PT, OT, or ST services beyond the initial evaluation and approved therapy sessions will be considered **medically appropriate** if **ALL** of the following criteria have been met:

A. Maintenance service level has not been achieved (Refer to Policy Guidelines);

B. Significant improvement must be demonstrated in objective measures including but not limited to **ANY** of the following:

1. Standardized assessments;
2. Non-imaging assessment; **or**
3. Speech specific testing (e.g., Repeat barium swallow; Fiberoptic endoscopic examination of swallowing (FEES), Weight gain);

C. Documentation of **ALL** of the following:

1. Showing continued improvement within the past treatment period;
2. An updated treatment plan; **and**
3. That the member is actively participating in therapy sessions.

Speech Therapy

IV. Speech Therapy services are considered **not medically necessary** for **ANY** the following indications:

A. Vocal cord polyps, as the usual recommended treatment is excision of the polyps;

B. Untreated conductive hearing loss, as diagnosis of and treatment for the hearing loss should first be provided;

C. Individual is receiving maintenance services (Refer to Policy Descriptions);

D. Oral myofunctional disorders (e.g., tongue thrust, deviant swallow, reverse swallow, visceral swallow);

E. Pragmatic language disorders/impairments.

Dysphagia and Feeding Difficulties

*For continuation of ST service (Refer to Policy Statement III).

V. Dysphagia in children with the potential functional ability to feed by mouth in need of ST is considered **medically appropriate** for and **EITHER** of the following indications:
   A. Evaluation of and diagnosis of aspiration or laryngeal penetration by a physician with expertise in the diagnosis and treatment of dysphagia;
   B. The child has a history of or is at high risk for recurrent aspiration or choking or has clinical signs/symptoms of aspiration.

VI. Feeding difficulties in children in need of ST is considered **medically appropriate** when **ANY** of the following criteria are met:
   A. Food refusal creating a risk of malnutrition, leading to the required use of enteral feeding or nutritional supplements; (Refer to Policy Guidelines)
   B. Nutritional status deficiencies that risk diet related diseases (e.g., rickets, scurvy).

Vocal Cord Dysfunction and Voice Therapy

* For continuation of ST service (Refer to Policy Statement III).

VII. Vocal Cord Dysfunction (VCD) treatment using ST is considered **medically appropriate**. (Treatment of VCD is not the same as voice therapy).

VIII. Voice therapy (Voice therapy is not the same as treatment of Vocal Cord Dysfunction) is considered **medically appropriate** for voice disorders when **ALL** of the following criteria has been met:
   A. When a pathological process has been identified (e.g., anatomic laryngeal/vocal cord abnormality);
   B. Other methods of treatment have been documented as ineffective.

IX. Voice therapy is considered **not medically necessary** for **ANY** of the following:
   A. Intensive behavioral therapy with or without the use of a computerized software program including but not limited to:
      1. Lee Silverman Voice Therapy, LSVT LOUD;
      2. SPEAK OUT!

Physical and Occupational Therapy

X. Non-skilled therapy services that do not require the expertise of an OT or PT therapist are considered **not medically necessary** and include but are not limited to **ANY** of the following:
   A. Passive range of motion (PROM) treatment that is not related to restoration of a specific loss of function;
   B. Treatments, given to an individual who presents without complications, including but not

limited to **ANY** of the following:

1. Infrared heat;
2. Whirlpool, paraffin or contrast baths;
3. Hubbard tank;
4. Cold, ice or heat packs;
5. Aquatic exercises;
6. Transcutaneous Electrical Nerve Stimulation (TENS);

C. Services that maintain function by using routine, repetitive procedures, exercise, conditioning or gym programs (land- or water-based), for stable, chronic conditions (lasting longer than three months since initial onset), such as fibromyalgia or chronic pain syndrome (chronic low-back pain);

D. Vasopneumatic compression, when used alone and without the need for skilled monitoring of potential adverse signs and symptoms;

E. Crutch training.

XI. The following PT or OT services are considered **not medically necessary** for **ANY** of the following:

A. Gait analysis;

B. Sensory integration therapy (SIT);

C. Hippotherapy, equine movement therapy, horseback riding;

D. Isokinetic testing with an isokinetic dynamometer (e.g., Biodex, Cybex II, Omnikinetic, Lido Active) in the assessment of muscle strength;

E. Programs solely for sports and/or recreational purposes (e.g., conditioning, strength training, and aquatic exercise programs such as water aerobics and water walking);

F. Maintenance programs (Refer to Policy Descriptions);

G. Work-related or workers' compensation programs (Refer to Policy Description, including but not limited to:

1. Work evaluation;
2. Work reconditioning, or work hardening programs;
3. Sheltered work programs; **or**
4. Vocational training.

XII. The following PT or OT Services are considered **investigational** for all indications, including but not limited to:

A. Dry needling;

B. Constraint-induced movement therapy (CIMT), as a sole measure of therapy.

1.01.03 Augmentative and Alternative Communication Systems (e.g., Speech Generating Devices)

7.01.84 Gender Reassignment and Treatments for Commercial and Medicare Members

2.01.13 Computerized Motion Diagnostic Imaging (CMDI)/Gait Analysis

7.01.11 Cosmetic and Reconstructive Procedures, which includes iontophoresis

10.01.02 Chiropractic Care

11.01.03 Experimental or Investigational Services

POLICY GUIDELINE(S)

I. OT, PT and ST services should be provided by the appropriate licensed therapist operating within their scope of practice. The therapist should address the functional needs of patients with physical impairments resulting from various causes, including disease, trauma, congenital anomalies, or prior therapeutic interventions. Treatment goals should be tailored to the patient's specific diagnosis, with an expectation of measurable improvement within a reasonable and predictable timeframe. The therapy provided should be specific, effective, and appropriate for the patient's diagnosis and physical condition.

II. Documentation for therapy services must contain a written plan of care, which should include:

A. Diagnosis, including severity level of diagnosis;

B. Specific statements of long- and short-term functional-based goals;

C. Measurable objectives based on standardized outcome measures defined in evaluation and reassessed during follow-up sessions;

D. A reasonable estimate of when the goals will be reached;

E. The specific treatment techniques and/or activities to be used in treatment (skilled intervention);

F. The frequency and duration of treatment; and

G. Prior level of function (PLOF), prior treatment, and current level of function (CLOF).

III. Classification of Impairments According to Severity

A. Mild Impairment:

1. Less than one (1) standard deviation from normal,

2. Appropriate for PT one (1) time per week.

B. Moderate Impairment:
   1. One (1)-to-two (2) standard deviations from normal,
   2. Appropriate for PT two (2) times per week.

C. Severe Impairment:
   1. More than two standard deviations from normal,
   2. Appropriate for PT three (3) times per week.

Individualized Education Program (IEP)

I. New York State Department of Health Early Intervention Program defines a developmental delay that has been measured by qualified personnel using clinical opinion, appropriate diagnostic procedures and/or instruments as documented as **ANY** of the following:
   A. A 12-month delay in one functional area;
   B. A 33% delay in one functional area or a 25% delay in each of two (2) areas;
   C. If appropriate standardized instruments are individually administered in the evaluation process, a score of at least 2.0 standard deviations below the mean in one functional area or a score of at least 1.5 standard deviations below the mean in each of two functional areas.

II. If outpatient therapies requested are in addition to the early intervention services, or school-based services noted in the IEP, or the provider does not feel that the child's needs are being met by the school-based services noted in the IEP, or when there is no IEP provided but it is documented that the child receives school-based services, or documentation must include rationale supporting the medical necessity of the additional outpatient services beyond what the child is already receiving at school as noted in the IEP.

III. Coverage is not available for services provided by school districts, as stipulated in a child's (preschool, ages 3-5 years, and school, ages 5-21 years) IEP, as the services are generally considered free care or a government program.
   A. When applicable, an IEP should be completed through the school district before a request for coverage is submitted to the Health Plan. If an IEP is not submitted, the request for speech therapy will be reviewed by the Health Plan for medical necessity in accordance with member's subscriber contract.
   B. Speech therapy services denied by the school district, including summer services, and not covered in a child's IEP will be reviewed by the Health Plan for medical necessity in accordance with member's subscriber contract.
   C. If a child is home-schooled, an assessment by the school district should be completed prior to submitting a request to the Health Plan for coverage. Requests for home-schooled children outside NYS will be decided in accordance with NYS laws; however, if an appeal is requested and another state's law is provided or cited, the case should be forwarded for legal review, to determine whether the other state's law should be applied.

D. Interim summer programs are provided by school districts for children whose handicapping conditions are severe enough to warrant a structured learning environment of 12 months' duration in order to maintain developmental levels. For preschool children, summer instruction must be available for those whose disabilities are severe enough to exhibit the need for a structured learning environment of 12 months duration to prevent substantial regression.

Speech Therapy Guidelines

IV. A maintenance program may be established when the response to treatment has plateaued, or restorative potential is judged insignificant after a reasonable period of time. In these situations, coverage is limited to the initial evaluation and the design of an appropriate maintenance program.

Tools for Assessment of Malnutrition:

- The World Health Organization (WHO) provides tools to assess malnutrition https://www.who.int/health-topics/malnutrition#tab=tab_1
- Based ideal weight for children on National Center for Health Statistics (NCHS) growth charts. Https://www.cdc.gov/growthcharts/
- The 2015 Academy of Nutrition and Dietetics/American Society for Parenteral and Enteral Nutrition consensus statement for indicators recommended for the identification and documentation of pediatric malnutrition (undernutrition) listed testing that should be used to assess malnutrition:
  - Food/Nutritional Intake;
  - Assessment of Energy and Protein Needs;
  - Growth Parameters;
  - Mid-Upper Arm Circumference;
  - Weight Gain Velocity;
  - Handgrip Strength; and
  - Documentation of Tanner Stages.

Standardized Tests for Evaluation of Speech Disorders (list is not all inclusive)

V. A common standard score scale has a mean (average) of 100 and a standard deviation of 15.
   A. Goldman Fristoe Test of Articulation (GFTA)
   B. Arizona Articulation Proficiency Scale (AAPS)
   C. Preschool Language Scale (PLS)
   D. Clinical Evaluation of Language Fundamentals (CELF)
   E. Clinical Assessment of Articulation and Phonology (CAAP)

F. Stuttering Severity Index (SSI)

G. Recessive Expressive Emergent Language (REEL)

H. Test of Language Development (TOLD-P)

Feeding Difficulties in Children

VI. Feeding difficulties in children are dependent on the child's specific diagnosis. Typically, up to four (4) visits are allowed for feeding difficulties in neurotypical children. However, additional speech therapy visits may be medically appropriate for neuroatypical children or significant aerodigestive abnormalities with feeding difficulties (e.g., autism).

DESCRIPTION

Maintenance Program

Maintenance program is defined as a program that consists of activities that preserve the patient's present level of function and prevent regression of that function. Maintenance begins when the therapeutic goals of a treatment plan have been achieved or when no additional functional progress is apparent or expected to occur.

Work-Related or Workers' Compensation Programs

- Work-related or workers' compensation are for conditioning primarily for return to work and not treatment of a medical condition.
- When PT or OT services are needed to treat a medical or surgical condition in order for a patient to return to work, services are covered by the New York State Vocational and Educational Services for Individuals with Disabilities (VESID) Program.

Speech Therapy

Speech therapy services are those necessary for the diagnosis and treatment of speech and language impairments/disorders that result in communication disabilities, as well as for the diagnosis and treatment of swallowing disorders, or dysphagia.

Speech disorders refer to those affecting the articulation of speech sounds, the fluency with which speech is produced, or quality.

Speech Disorders

- Articulation disorders are also called phonological disorders and include:
    - Motor speech disorders resulting from damage to the central or peripheral nervous system (e.g., cerebral vascular accident, traumatic brain injury, or neurogenic disorders such as Parkinson's disease, Huntington disease, amyotrophic lateral sclerosis, and perinatal conditions); and
    - Functional articulation disorders, which have no known cause or result from causes other than known neurological insults or physical abnormalities. Functional articulation disorders account for the majority of articulation disorders in children.

- Fluency disorders are also referred to as stuttering, involve the interruption in the flow of speaking manifested as an atypical rate, rhythm, repetitions in sounds, syllables, words, and phrases; or some combination of these.
- Voice disorders are characterized by abnormal pitch, loudness, resonance, quality, or duration of voice, or by an inability to use voice, or some combination of these, result from overuse or misuse of vocal cords, medical condition or psychological disorder impacting the ability to communicate effectively.
- Language disorders are disorders of impaired comprehension and/or use of spoken, written, and/or other symbol systems used for communication (e.g., aphasia secondary to cerebral vascular accident, dementia, hearing impairment).
- Pragmatics is the system of combining the form (phonology, morphology, and syntax) and content (semantics) of language into functional and socially appropriate communication. A person with a pragmatic language disorder/impairment may say inappropriate or unrelated things during a conversation, tell stories in a disorganized way, or have little variety in the use of language.

Other Common Speech Terms

- Aphasia is defined as the absence or impairment of the ability to communicate through speech, writing, or signs because of brain dysfunction.
- Aphonia is defined as a loss of speech sounds from the larynx.
- Apraxia is defined as the inability to form words or speak, despite the ability to use oral and facial muscles to make sounds.
- Dysarthria is defined as impairments or clumsiness in the uttering of words due to diseases that affect the oral, lingual, or pharyngeal muscles.
- Dysphonia is defined as any impairment of the voice or speaking ability.
- Neurosensory Hearing Loss is defined as a decreased ability to perceive sounds as compared to normal.

Voice Therapy

Vocal cord dysfunction (VCD), also known as paradoxical vocal fold movement- is a respiratory disorder characterized by paradoxical closure of the vocal cords during the respiratory cycle that leads to airway obstruction. Symptoms can range from wheezing to stridor. VCD can be mistaken for asthma and is distinguished from asthma by the performance of a pulmonary function test and laryngoscopy. VCD is often treated with speech therapy, relaxation techniques, or psychotherapy.

Lee Silverman Voice Therapy, LSVT LOUD has been proposed as an intensive behavioral voice therapy program for individuals with Parkinson disease and other neurological disorders and is aimed at improving the vocal loudness of these patients. The LSVT Companion System may be used as a technical adjunct to the program, to complement person-to-person voice therapy. The sound produced by a patient's voice is received by a calibrated microphone and converted to a visual display

that consists of different visual and auditory feedback. The patient is given a target range of both vocal intensity (loudness) and fundamental frequency (pitch) and instructed to maintain a given loudness and or pitch for a given duration.

SPEAK OUT! is a program designed for individuals with Parkinson's disease to improve speech (speaking with intent) and swallowing. The exercises used target vocal function and speech clarity and moving it from an automatic function to an intentional task.

Dysphagia

Dysphagia is defined as difficulty swallowing. It is a frequently occurring impairment for children with disabilities because many disabling conditions are associated with oropharyngeal or esophageal dysfunction. The workup for dysphagia usually includes an evaluation by a speech therapist and may also include a video fluoroscopic barium study (often referred to as a cookie swallow) or a fiber-optic endoscopic evaluation of swallow. Speech and occupational therapists often collaborate in feeding therapy for children with poor oral motor and swallowing skills on the basis of the child's needs and the expertise of the providers involved.

Nutritional status deficiency refers to an imbalance in the intake of essential nutrients required by the body.

Physical Therapy

PT is the treatment of disease or injury by the use of therapeutic exercise and other interventions that focus on improving posture, locomotion, strength, endurance, balance, coordination, joint mobility, flexibility, and the ability to perform the functional activities of daily living, as well as the relief of pain. PT is a short-term therapy that is expected to result in significant, measurable improvements.

Baseline objective measurement(s) is/are essential to determine clinical effectiveness of all PT interventions. Clinical assessment of the patient's strength, prior to the initiation of PT, is essential to determining the therapeutic effectiveness of PT. Assessment data is obtained through a variety of standardized tests (e.g., measurement, functional performance, and manual or isokinetic muscle evaluation).

Hippotherapy (Equine-Assisted Therapy) is a treatment strategy that uses the movement of horses to engage sensory, neuromotor, and cognitive systems to achieve functional outcomes. It has been proposed as a therapy for individuals with impaired walking or balance.

Isokinetic exercise involves muscle use in an action that results in a movement without changing angular velocity. It involves the accommodation of resistance throughout the range of motion, to closely resemble normal action of muscle. Dynamometers are pieces of equipment that use hydraulics to maintain constant velocity and are controlled by a computer and associated software to measure joint flexion and extension via torque, typically of the knee, but can be adapted for other joints.

Dry needling refers to a procedure whereby a fine needle is inserted into the trigger point, to induce a twitch response and relieve pain. Research suggests that dry needling may improve pain control and reduce muscle tension in neck and/or shoulder pain, plantar heel pain, temporomandibular myofascial pain, and other conditions. Dry needling can be deep or superficial. Deep dry needling is

believed to inactivate trigger points by eliciting contraction and subsequent relaxation of the muscle via a spinal cord reflex. Superficial needing is believed to activate mechanoreceptors and have an indirect effect on pain by inhibiting C-fiber pain impulses.

Sensory integration therapy (SIT) is a form of PT that has been investigated as a method of treatment for developmental disorders in patients with established sensory processing dysfunction, as in autism spectrum disorder (ASD). Sensory integration therapy is aimed at improving the way the brain processes and organizes sensations, as opposed to teaching higher-order skills. Therapy usually involves activities that provide vestibular, proprioceptive, and tactile stimuli, which are selected to match specific sensory processing deficits of the child. For example, swings are commonly used to incorporate vestibular input, while trapeze bars and large foam pillows or mats may be used to stimulate somatosensory pathways of proprioception and deep touch. Tactile reception may be addressed through a variety of activities and surface textures involving light touch.

Occupational Therapy (OT)

Occupational Therapy (OT) is a short-term form of rehabilitation therapy involving the treatment of individuals of all ages with functional deficits resulting from injury, disease, or birth. Occupational therapists assess all components of function (strength, range of motion, sensation, coordination, cognition, perception, vision, memory, judgment, safety, etc.) and work with the individual through the use of goal-directed, graded activity and exercise to improve skills.

Sensory Integration Therapy (SIT) is a form of OT that has been investigated as a method of treatment for autism, intellectually disable, or learning disabilities. Sensory integration therapy is aimed at improving the way the brain processes and organizes sensations, as opposed to teaching higher-order skills.

Constraint-Induced Movement Therapy (CIMT) is proposed as a method of therapy to help patients with neurological disorders (e.g., cerebral palsy, congenital hemiplegia, stroke) regain the use of dysfunctional limb(s). CIMT involves restraint of the unaffected limb and intensively engaging the affected limb in repetitive exercises, which results in the new neural pathways being generated in the brain.

SUPPORTIVE LITERATURE

Speech Therapy

Sackley et al (2024) conducted a multicenter, three arm, unblinded, randomized controlled trial involving 388 people with Parkinson's and dysarthria to assess the clinical effectiveness of two speech and language therapy approaches versus no speech and language therapy. Participants were randomly assigned to one of three groups: Lee Silverman Voice Treatment (LSVT LOUD, n=130), NHS speech and language therapy (n=129), or no therapy (n=129). The primary outcome was self-reported Voice Handicap Index (VHI) at three months. Participants receiving LSVT LOUD reported lower VHI scores at three months than those who did not receive speech and language therapy (−8.0 points; 99% CI −13.3 to −2.6). NHS therapy showed no significant difference from no therapy (1.7 points; CI−3.8 to 7.1). Patients in the LSVT LOUD group also reported LVH index scores than did those randomized to NHS speech and language therapy (−9.6 points; CI−14.9 to −4.4). Adverse

events, mainly vocal strain, were reported in 93 LSVT LOUD participants and 46 NHS therapy participants; none were serious. LSVT LOUD was more effective than both NHS therapy and no therapy in reducing voice-related disability. NHS therapy showed no clear benefit over no treatment.

Namasivayam et al (2021) conducted a two-arm randomized control trial studying the effectiveness of Prompts for Restructuring Oral Muscular Phonetic Targets (PROMPT) in children with severe speech motor delays (SMD). The study was comprised of 49 children with SMD. The intervention group received 45 min of PROMPT intervention two times a week for 10 weeks or were waitlisted for the same duration and received only home training instructions. Outcome measures for speech motor control, articulation, speech intelligibility, and functional communication were assessed at baseline and at 10 weeks. PROMPT interventions were found to be clinically effective intervention for children with SMD.

Behrman et al (2020) conducted a prospective study on 40 individuals with idiopathic Parkinson's disease (PD) to assess the outcome of the SPEAK OUT! and the LOUD Crowd therapy programs. Of the 40 individuals, 12 received 40-minute sessions, 3 times per week of SPEAK OUT!, for 4 weeks. Assessments were conducted at baseline, within one week and 6 weeks after completion of the SPEAK OUT! sessions, while also participating in LOUD Crowd. Twenty-five (25) adults without communication disorders were assessed at the same schedule as the SPEAK-OUT! recipients. In the PD group reading and monologue intensity increased significantly. The mean values of intensity for the PD group were lower than those of the control group at baseline, but posttherapy values for the two groups were equivalent. Posttherapy, it was determined that there is evidence of effectiveness of this program on hypokinetic dysarthria secondary to PD.

Hippotherapy

The literature regarding hippotherapy consists of systematic reviews, randomized trials, and case series involving individuals with cerebral palsy, multiple sclerosis, stroke or gait and balance disorders. The randomized trials are generally small, can be described as having significant methodologic problems, and have not demonstrated that hippotherapy is superior to alternative therapies. Therefore, the evidence is insufficient to determine that it results in an improvement in the net health outcome.

Isokinetic Testing

Several isokinetic dynamometers have received FDA approval. Published literature suggests that due to the large variations in testing methods, isokinetic dynamometry has not been medically proven to improve net health outcomes or to be more effective than established methods of assessment of muscle strength. The effectiveness of isokinetic dynamometry has not been demonstrated outside the investigational setting.

Dry Needling

Dry needling has been investigated in randomized controlled trials (RCTs) and systematic reviews. Reviewers have summarized that studies have not associated dry needling with reductions in shoulder or neck pain compared to other modalities.

Young et al (2024) conducted a randomized, single blinded, multicenter, parallel group trial

comparing the effects of adding thrust spinal manipulations and electrical dry needling to conventional physical therapy in patients with lumbar spinal stenosis (LSS). Over 34 months, 128 patients from 12 outpatient clinics in eight states were assessed using Numeric Pain Rating Scale (NPRS) and the Oswestry Disability Index (ODI) (primary outcomes) and the Roland Morris Disability Index (RMDI), Global Rating of Change (GROC), and medication intake (secondary outcome) at 2 and 6 weeks and 3 months. At 3 months, the MEDNCPT group experienced greater reductions in overall pain and related disability compared to the conventional physical therapy (CPT) group. At 3 months, significantly more patients in the MEDNCPT group reported a successful outcome (GROC≥+5) than the CPT group. No significant differences were observed at earlier follow-ups. Limitations included the lack of sham-needling comparison group, the MEDNCPT group received additional treatments compared to the CPT group, the use of separate region-specific pain scores.

Sensory Integration Therapy (SIT)

There is insufficient evidence to permit conclusions regarding the effectiveness of SIT or whether SIT improves the net health outcome in children with autism and developmental impairments. Only one study was published for SIT in autistic children, and three studies were published for SIT in developmentally delayed children; the validity of all four studies is questionable. The evidence indicates that SIT does not improve the net health outcome in learning-disabled children when compared to alternative treatments or no treatment at all.

Occupational Therapy

García-Pérez et al (2024) conducted a prospective, randomized controlled clinical trial in 60 adults who have suffered a stroke and were discharged home and what the effectiveness of an early OT intervention programs (EOTIPS). Participants were assigned to the experimental group (n=30) were included in EOTIPS and were compared to a control group (n=30). Evaluations assessed quality of life (Stroke and Aphasia Quality of Life Scale [SAQOL-39]), functional independence (Modified Rankin Scale [mRS]), perceptual-cognitive skills (Montreal Cognitive Assessment [MoCA]), upper limb function (Fugl Meyer Assessment [FMA]), mobility (Berg Balance Scale [BBS] and Timed Up & Go [TUG]), communication skills (Communicative Activity Log [CAL]) and mood disorders (Beck Depression Inventory–II [BDI-II]); completed within two weeks post-stroke and at three month follow-up. Intent-to-treat analysis, considering all participants (dropouts as failures), and efficacy analysis, considering only end-of-treatment participants. Participants in the intervention group showed a significant better evolution in the main outcome measure of quality of life (SAQOL-39 p = .029), as well as for independence (mRSp = .004), perceptual-cognitive skills (MoCA p = .012) and symptoms of depression (BDI-II p = .011) compared to the control group. The study supports EOTIPS as effective in improving post-stroke recovery. Limitations included lack of therapist blinding, inclusion of only mild-to-moderate stroke cases, variability in rehab sessions, and inconsistent caregiver support.

Sensory Integration Therapy (SIT)

There is insufficient evidence to permit conclusions regarding the effectiveness of SIT or whether SIT improves the net health outcome in children with autism and developmental impairments. Only one study was published for SIT in autistic children, and three studies were published for SIT in

intellectually disabled children; the validity of all four studies is questionable. The evidence indicates that SIT does not improve the net health outcome in learning-disabled children when compared to alternative treatments or no treatment at all.

Randall et al (2024) conducted a two-arm RCT to assess the clinical and cost-effectiveness of manualized Sensory Integration Therapy (SIT) for autistic children with sensory processing difficulties. They recruited 138 children and carers (92% of those screened), with retention rates of 77.5% at 6 months and 69.9% at 12 months. Intervention fidelity was high, with 78.3% receiving a sufficient dose, though session attendance varied. Descriptive statistics covered recruitment, demographics, adherence, and adverse effects—none were reported. Qualitative interviews with carers and therapists found the intervention generally acceptable, despite logistical barriers like scheduling, travel, and COVID-19. The process evaluation highlighted contextual factors affecting effectiveness and emphasized the importance of caregiver involvement and individualized outcomes in future research.

Constraint-Induced Movement Therapy (CIMT)

There is insufficient evidence to permit conclusions regarding the effectiveness of CIMT for any indication. The majority of studies address the utilization of CIMT in either cerebral palsy, congenital hemiplegia, or stroke rehabilitation. Several studies, systematic reviews and meta-analyses have recently been published. They conclude that further rigorous, well-designed, randomized, controlled studies addressing CIMT are needed, to determine the efficacy of its use.

Reddy et al (2022) conducted a systematic review and meta-analysis aiming to delineate the effect of various lower extremity CIMT (LECIMT) protocols on gait speed, balance, and cardiovascular outcomes. For this study, clinical trials involving stroke populations in different stages of recovery, greater than 18 years old, and treated with LECIMT were considered, only ten studies were included. CIMT, when compared to controlled interventions, showed superior or similar effects. The effect of LECIMT on gait speed and balance were non-significant, with mean differences (SMDs) of 0.13 and 4.94 and at 95% confidence intervals (Cis) of (-0.18–0.44) and (-2.48–12.37), respectively. In this meta-analysis, the authors observed that despite the fact that several trials claimed the efficacy of LECIMT in improving lower-extremity functions, gait speed and balance did not demonstrate a significant effect size favoring LECIMT. Therefore, CIMT treatment protocols should consider the patient's functional requirements, cardinal principles of CIMT, and cardiorespiratory parameters.

PROFESSIONAL GUIDELINE(S)

In the American Speech-Language-Hearing Association (ASHA) 2015 Speech-Language Pathology Medical Review Guidelines they state that "eligibility for services or evaluation is indicated if one or more of the following factors are present:

- When a referral is made from a teacher, family member, or a professional in hearing, speech and language.
- Failure to pass a screening assessment for function of communication and/or swallowing.
- Individual is unable to communicate functionally or optimally across environments.

- Individual is unable to swallow to maintain adequate nutrition or hydration.
- Evaluation by ASHA-certified speech-language pathologist shows the presence of a speech or swallowing disorder.
- Individual's communications skills are not comparable to others of the same age, gender, ethnicity, or cultural and linguistic background.
- Communication skills are negatively affecting health, safety, social, emotional, educational or vocational status.
- Swallowing skills negatively affect his or her nutritional health or safety.
- Family or guardian want to achieve and/or maintain optimal communication and/or swallowing skills.
- Individual or family is looking for services to enhance communications skills."

The 2016 Guidelines for Adults Stoke Rehabilitation and Recovery by the American Heart Association (AHA) and American Stroke Association (ASA) (Winstein et al 2016), which were accepted by the ASHA state:

- "Speech and language therapy is recommended for individuals with aphasia. (class I, level of evidence A)
- Computerized treatment may be considered to supplement treatment provided by a speech language pathologist." (class IIb, level of evidence A)

In June 2012, the American Academy of Pediatrics (AAP) issued a policy statement indicating that treatment "with the use of sensory-based therapies may be acceptable as one of the components of a comprehensive treatment plan. However, parents should be informed that the amount of research regarding the effectiveness of sensory integration therapy is limited and inconclusive."

Becker et al (2015) presented The Academy of Nutrition and Dietetics/American Society for Parenteral and Enteral Nutrition consensus statement for indicators recommended for the identification and documentation of pediatric malnutrition (undernutrition). The recommendations are as follows:

- "Food/Nutritional Intake- Completed by history and/or direct observation for food and/or nutrients consumed.
- Assessment of Energy and Protein Needs- measured by indirect calorimetry (most precise) or estimated through the use of standard equations.
- Growth Parameters-Growth should be monitored at regular intervals and are typically expressed and reported in comparison with population data (normally in percentiles). Standard deviation comparisons are recommended for tracking and assessing nutritional status:
    - In children less than 36 months of age- measures of growth include length-for-age, weight-for-age, head circumference-for-age, and weight-for-length.

  - In children ages 2–20 years, standing height-for-age, weight-for-age, and body mass index (BMI)-for-age.
- Weight Gain Velocity- defined as the rate of change in weight or length/height over time.
- Mid-Upper Arm Circumference- has been correlated to BMI in children and adults. It is important measurement in individuals whose weight may be affected by fluid retention (edema, ascites or steroids).
- Handgrip Strength- using a handheld dynamometer, it measures the maximum strength of the hand and the forearm muscles.
- Documentation of Tanner Stages-Because of the variability in genetic determinants for the onset of puberty, using the Tanner staging is limited (Becker 2015)."

REGULATORY STATUS

As of January 1, 2014, the Patient Protection and Affordable Care Act (PPACA) required all health insurers to provide coverage for essential health benefits, including habilitative services. Under PPACA, habilitative services are health care services that help a person keep, learn or improve skills and functioning for daily living and include the management of limitations and disabilities, including services or programs that help maintain or prevent deterioration in physical, cognitive, or behavioral function.

Under federal law, all health insurers must provide essential health benefits in the individual and small group markets, including habilitative services. The law defines habilitative services as health care services that help a person keep, learn or improve skills and functioning for daily living and include the management of limitations and disabilities, including services or programs that help maintain or prevent deterioration in physical, cognitive, or behavioral function.

Certain contracts only cover short-term therapy services for a limited number of visits per condition, per lifetime, or per contract year. These limits generally apply to all therapies combined (PT, OT and ST). The visit limits do not apply when PT, OT or ST are for the treatment of a Mental Disorder (including autism spectrum disorder). Mental Disorder is defined in the most recent edition of the Diagnostic and Statistical Manual of Mental Disorders.

New York State Laws

Under New York State law, all insured contracts providing physician services, or providing medical, major medical, or similar comprehensive-type coverage, must provide coverage for the screening, diagnosis, and treatment of autism spectrum disorders when prescribed or ordered by a licensed physician or a licensed psychologist for medically necessary services. Treatment includes services provided by a licensed or certified speech therapist, occupational therapist, physical therapist, and social worker, when the policy generally provides such coverage. Therapeutic treatment must include care that is deemed habilitative or non-restorative.

New York State law restricts the practice of PT to licensed physical therapists or certified physical therapist assistants. Individuals who are not licensed or certified may not provide PT services. Athletic trainers are not licensed or otherwise authorized in New York State to practice PT.

The New York State Vocational and Educational Services for Individuals with Disabilities (VESID) Program covers PT or OT services that are needed to treat a medical or surgical condition for a patient to return to work.

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
20560 (E/I)	Needle insertion(s) without injection(s); 1 or 2 muscle(s)
20561 (E/I)	Needle insertion(s) without injection(s); 3 or more muscle(s)
92507	Treatment of speech, language, voice, communication, and/ or auditory processing disorder; individual
92508	Treatment of speech, language, voice, communication, and/ or auditory processing disorder; group, Two (2) or more individuals
92521	Evaluation of speech fluency (e.g., stuttering, cluttering)
92522	Evaluation of speech sound production (e.g., articulation, phonological process, apraxia, dysarthria)
92523	Evaluation of speech sound production (e.g., articulation, phonological process, apraxia, dysarthria); with evaluation of language comprehension and expression (e.g., receptive and expressive language)
92524	Behavioral and qualitative analysis of voice and resonance
92526	Treatment of swallowing dysfunction and/or oral function for feeding
92610	Evaluation of oral and pharyngeal swallowing function
96105	Assessment of aphasia (includes assessment of expressive and receptive speech and language function, language comprehension, speech production ability, reading, spelling, writing, e.g., by Boston Diagnostic Aphasia Examination) with interpretation and report, per hour

Code	Description
97010	Application of a modality to 1 or more areas; hot or cold packs
97012	traction, mechanical
97014	electrical stimulation (unattended)
97016	vasopneumatic devices (NMN when used without skilled monitoring)
97018	paraffin bath
97022	whirlpool
97024	diathermy (e.g., microwave)
97026	infrared
97028	ultraviolet
97032	electrical stimulation (manual), each 15 minutes
97033	iontophoresis, each 15 minutes
97034	contrast baths, each 15 minutes
97035	ultrasound, each 15 minutes
97036	Hubbard tank, each 15 minutes
97110	Therapeutic procedure, 1 or more areas, each 15 minutes; therapeutic exercises to develop strength and endurance, range of motion and flexibility
97112	neuromuscular reeducation of movement, balance, coordination, kinesthetic sense, posture, and/or proprioception for sitting and/or standing activities
97113	aquatic therapy with therapeutic exercises
97116	gait training (includes stair climbing)
97140	Manual therapy techniques (e.g., mobilization/ manipulation, manual lymphatic drainage, manual traction), 1 or more regions, each 15 minutes
97150	Therapeutic procedure(s), group (2 or more individuals)

Code	Description
97161	Physical therapy evaluation: low complexity
97162	Physical therapy evaluation: moderate complexity
97163	Physical therapy evaluation: high complexity
97164	Re-evaluation of physical therapy established plan of care
97168	Re-evaluation of occupational therapy established plan of care, requiring these components: An assessment of changes in patient functional or medical status with revised plan of care; An update to the initial occupational profile to reflect changes in condition or environment that affect future interventions and/or goals; and A revised plan of care. A formal reevaluation is performed when there is a documented change in functional status or a significant change to the plan of care is required. Typically, 30 minutes are spent face-to-face with the patient and/or family.
97530	Therapeutic activities, direct (one-on-one) patient contact (use of dynamic activities to improve functional performance), each 15 minutes
97533 (NMN)	Sensory integrative techniques to enhance sensory processing and promote adaptive responses to environmental demands, direct (one-on-one) patient contact, each 15 minutes
97535	Self-care/home management training (e.g., activities of daily living (ADL) and compensatory training, meal preparation, safety procedures and instructions in use of assistive technology devices/adaptive equipment) direct one-on-one contact, each 15 minutes
97537 (NMN)	Community/work reintegration training (e.g., shopping, transportation, money management, avocational activities and/or work environment/modification analysis, work task analysis), direct one-on-one contact, each 15 minutes
97542	Wheelchair management (e.g., assessment, fitting, training), each 15 minutes
97545 (NMN)	Work hardening/conditioning; initial two hours
97546 (NMN)	each additional hour

Code	Description
97750	Physical performance test or measurement (e.g., musculoskeletal, functional capacity), with written report, each 15 minutes Note: Considered NMN when used for isokinetic testing or vibromyography.
97760	Orthotic(s) management and training (including assessment and fitting when not otherwise reported), upper extremity (ies), lower extremity(ies) and/or trunk, initial orthotic(s) encounter, each 15 minutes
97761	Prosthetic(s) training, upper and/or lower extremity(ies), initial prosthetic(s) encounter, each 15 minutes
97763	Orthotic(s)/prosthetic(s) management and/or training, upper extremity(ies), and/or trunk, subsequent orthotic(s)/prosthetic(s) encounter, each 15 minutes

MEDICAL POLICY

Medical Policy Title	**Thermal Ablation for Solid Tumor Treatment**
Policy Number	**7.01.111**
Current Effective Date	**September 1, 2026**
Next Review Date	**August 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service.

(Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Radiofrequency Tumor Ablation

A. Radiofrequency ablation (RFA) is considered a **medically appropriate** treatment option for **hepatocellular carcinoma** for **EITHER** of the following conditions:

1. Individual is not a surgical candidate (e.g., location of lesion[s], existence of comorbid conditions) and Milan criteria is met (e.g., a single tumor of less than or equal to 5 cm or up to three [3] lesions no greater than 3 cm in diameter);
2. As a bridge to transplant when the individual meets liver transplant criteria and is awaiting liver transplantation.

B. RFA is considered a **medically appropriate** treatment option for the **primary treatment of hepatic metastases** for **ALL** of the following conditions:

1. Individual is not a surgical candidate (e.g., location of lesions, existence of comorbid conditions);
2. Metastases meet the Milan criteria (e.g., a single tumor of less than or equal to 5 cm or up to three [3] lesions no greater than 3 cm in diameter);
3. The patient has no evidence of uncontrolled extrahepatic systemic metastatic disease.

C. Percutaneous RFA of an **osteoid osteoma** is considered a **medically appropriate** alternative to surgical excision when the individual cannot be managed successfully with medical management.

D. RFA is considered **medically appropriate** when utilized for palliation of pain in individuals with **osteolytic bone metastases** who have failed or are poor candidates for standard treatments such as opioids or radiation.

E. RFA of **localized renal cell carcinoma** is considered **medically appropriate** when the following criteria are met:

1. Lesion size is 4 cm or less in diameter; and **EITHER**

a. The individual is not a surgical candidate (e.g., location of lesion[s], existence of comorbid conditions); **or**

b. Treatment is necessary to preserve kidney function in individuals with significantly impaired renal status (i.e., the individual has one (1) kidney or renal insufficiency as defined by a glomerular filtration rate of <60mL/min/m2); and standard treatment is likely to substantially worsen kidney function.

F. RFA is considered **medically appropriate** to treat **non-small cell lung cancer (NSCLC**) when **BOTH** of the following conditions are met:

1. Isolated and peripheral lesion is 3 cm or less in size;
2. Individual is not a surgical candidate. Surgical resection or radiation treatment with curative intent is considered appropriate based on stage of disease however, medical co-morbidity renders the individual unfit for those interventions.

G. RFA is considered **medically appropriate** to treat **non-pulmonary tumor(s) metastatic to the lung** for any of the following conditions:

1. Surgical resection or radiotherapy is likely to worsen pulmonary status substantially and ablation would be necessary to preserve lung function;
2. The individual is not a surgical candidate (e.g., location of lesion[s], existence of comorbid conditions), and **ALL** of the following criteria are met:
   a. Tumor size is 3 cm or less;
   b. There is no evidence of extrapulmonary metastases;
   c. There are no more than three (3) tumors per lung to be ablated;
   d. Tumors are amenable to complete ablation; **and**
   e. Twelve months have elapsed since the last ablation.

H. Laparoscopic, transcervical ultrasound-guided RFA (e.g., the Acessa System, Sonata Device) is considered **medically appropriate** as an alternative to hysterectomy or myomectomy for the treatment of **uterine fibroid tumors**, when **ALL** the following criteria are met:

1. Individual is aged 18 years or older;
2. Individual is premenopausal;
3. Evidence from ultrasound demonstrates that fibroids are less than 10 cm in diameter for laparoscopic RFA with Acessa or 7 cm for transcervical RFA with Sonata;
4. Symptoms are persistent, directly attributed to the uterine fibroid(s), and include **ANY** of the following:
   a. Excessive menstrual bleeding (menorrhagia);
   b. Pelvic pain or pressure;

c. Gastrointestinal symptoms related to compression of the bowel (e.g., constipation, bloating);

d. Urinary symptoms related to compression of the ureter or bladder (e.g., urinary frequency, urgency); **or**

e. Dyspareunia (pain during sexual relations).

I. RFA is considered **investigational** as a treatment method for any other solid tumors, including, but not limited to pancreatic, thyroid, and breast tumors.

II. Cryosurgical Ablation

A. Cryosurgical ablation (CA) of **localized renal cell carcinoma** is considered **medically appropriate** for the following conditions:

1. Lesion size is 4 cm or less in diameter; and **EITHER**

a. The individual is not a surgical candidate (e.g., location of lesion[s], existence of comorbid conditions); **or**

b. Treatment is necessary to preserve kidney function in individuals with significantly impaired renal status (i.e., the individual has one (1) kidney or renal insufficiency as defined by a glomerular filtration rate of <60mL/min/m2); and standard treatment is likely to substantially worsen kidney function.

B. CA may be considered a **medically appropriate** treatment option for individuals with **lung cancer** for the following conditions:

1. Individual requires palliation for a central airway obstructing lesion;

2. Diagnosis is early-stage non-small cell lung cancer and **BOTH** of the following are met:

a. Individual is not receiving stereotactic radiotherapy or definitive radiation therapy; **and**

b. Individual is considered "high risk" as a poor surgical candidate (see Professional Guidelines section; NCCN Guidelines for NSCLC, for guidance on what is considered "high risk").

C. CA of desmoid tumors is considered **medically appropriate** as part of active therapy when tumor is progressive, morbid or symptomatic.

D. CA of an **osteoid osteoma** is considered a **medically appropriate** alternative to surgical excision when the individual cannot be managed successfully with medical management.

E. CA is considered **medically appropriate** when utilized for palliation of pain in individuals with osteolytic bone metastases who have failed or are poor candidates for standard treatments such as opioids or radiation.

F. CA is considered **investigational** as a treatment method for any other tumor, including but not limited to, primary/metastatic liver malignancies, breast tumors (benign and malignant),

and pancreatic cancer.

III. Microwave Ablation

A. Microwave ablation (MWA) is considered **medically appropriate for primary or metastatic hepatic tumors** when **BOTH** of the following conditions are met:

1. Individual is not a surgical candidate (e.g. location of lesion[s], existence of comorbid conditions);
2. Milan criterion is met (e.g., a single tumor of less than or equal to 5 cm or up to three [3] nodules no greater than 3 cm in diameter).

B. MWA is considered **medically appropriate** for **primary or metastatic lung tumors** when **ALL** the following conditions are met:

1. Individual is not a surgical candidate (e.g. location of lesion[s], existence of comorbid conditions);
2. Individual will not be receiving stereotactic radiotherapy or definitive radiation therapy;
3. Treatment is for a tumor that is 3 cm or less in size.

C. MWA is considered **medically appropriate** for renal cell carcinoma when **ALL** the following conditions are met:

1. Individual is not a surgical candidate (e.g. location of lesion[s], existence of comorbid conditions);
2. Biopsy of lesions is recommended to be done prior to or at time of ablation;
3. Treatment is for a tumor that is 3 cm or less in size.

D. MWA is considered **medically appropriate** when utilized for palliation of pain in individuals with osteolytic bone metastases who have failed or are poor candidates for standard treatments such as opioids or radiation.

E. MWA for the treatment of primary or metastatic tumors other than liver, lung, kidney or bone is considered **investigational**.

POLICY GUIDELINE(S)

Documentation should include the relevant history and physical demonstrating the tumor type, the rationale of why the tumor is unresectable (if applicable), size of tumor(s) to be treated, and ablation modality to be utilized.

DESCRIPTION

Surgical resection is the standard treatment for many solid tumor types, and despite advances in surgical techniques, many patients are either considered inoperable for surgery or prefer a nonsurgical minimally invasive local treatment. For individuals who meet specific criteria given the location, tumor size and type, thermal ablation can be offered as an alternative. The most common ablative modalities are radiofrequency ablation (RFA), microwave ablation (MWA) and Cryoablation (CA). RF and MWA utilize thermal/heat-based techniques and CA uses thermal/cold-based techniques (i.e., freezing) to destroy tissues. Per the National Comprehensive Cancer Network (NCCN), each ablation energy modality has advantages and disadvantages, therefore, determination of the modality utilized should take into consideration the size and location of the target tumor, risk of complication, as well as local expertise and/or operator familiarity.

Radiofrequency Ablation

RFA is the oldest and most frequently utilized thermal ablative technique and can be administered percutaneously, by open or laparoscopic surgery. This modality relies on heat to destroy tumors by thermal coagulation and protein denaturation. High frequency alternating current flows from un-insulated electrode tips into surrounding tissue. As the tissue ions attempt to follow the change in direction of the alternating current, ionic agitation results in frictional heating. The tissue surrounding the electrode, rather than the electrode itself, is the primary source of heat. It is presumed that tissue heating drives extracellular and intracellular water out of the tissue, resulting in coagulative necrosis.

RFA is typically used to treat inoperable tumors or to treat patients who are ineligible for surgery due to advanced age or co-morbidities. RFA was developed initially to treat inoperable tumors of the liver and is now utilized as a minimally invasive treatment alternative for other solid tumors, such as lung, renal, bone, and uterine fibroids.

Cryosurgical Ablation

Cryosurgical ablation (CA) is a method of thermal tumor ablation in which subfreezing temperatures are delivered through penetrating or surface cryoprobes in which a cryogen is circulated. Cell death is caused by direct freezing, denaturation of cellular proteins, cell membrane rupture, cell dehydration and ischemic hypoxia. Cryosurgical ablation may be used for the destruction of metastatic tumors in situ or for the destruction of microscopic residual carcinoma in the case of close surgical margins. It may be performed as an open surgical technique or as a closed procedure.

Several CA devices have been cleared for marketing by the FDA through the 510(k) process for use in open, minimally invasive, or endoscopic surgical procedures in the areas of general surgery, urology, gynecology, oncology, neurology, dermatology, proctology, thoracic surgery, and surgeries of the ear, nose, and throat. Examples include: Cryocare Surgical System (Endocare); CryoGen Cryosurgical

System (Cryosurgical); CryoHit (Galil Medical) for the treatment of breast fibroadenoma; IceSense3, ProSense, MultiSense Systems (IceCure Medical); SeedNet System (Galil Medical); and Visica System (Sanarus Medical). FDA product code: GEH.

CA has been investigated for its efficacy in the treatment of liver, lung, kidney, bone, breast, cervical cancer, neuroendocrine tumors and prostate cancer. CA for the treatment of prostate cancer is not addressed in this policy.

Microwave Ablation

Microwave ablation (MWA) is similar to RFA and CA as a form of thermal ablation. However, MWA has potential advantages over both. MWA uses microwave energy to heat and coagulate the tissue adjacent to the probe, resulting in a small, 2 cm to 3 cm elliptical area of tissue ablation. In tumors greater than 2 cm in diameter, 2 to 3 antennas may be used simultaneously to increase the targeted area and shorten the operative time. The use of multiple antennas can reduce the operative time by 20%-30%. The higher temperatures reached with MWA (>100°C) can overcome the "heat sink" effect occurring in RFA, in which tissue cooling occurs from nearby blood flow in large vessels, potentially resulting in incomplete tumor ablation. Microwave ablation does not rely on the conduction of electricity for heating and, therefore, does not flow electrical current through patients. Grounding pads are not required because there is no risk of skin burns. Additionally, MWA does not produce electric noise, which allows ultrasound guidance during the procedure without interference, unlike RFA.

Multiple MWA devices have been cleared for marketing by the FDA through the 510(k) process. These devices are indicated for soft tissue ablation, including partial or complete ablation of nonresectable liver tumors. Some devices are specifically cleared for use in open surgical ablation, percutaneous ablation, or laparoscopic procedures. The FDA used determinations of substantial equivalence to existing radiofrequency and MWA devices to clear these devices. Examples include: MedWaves Microwave Coagulation/Ablation System (MedWaves Inc.), MicroThermX Microwave Ablation System (BSD Medical Corporation), Emprint Ablation System (Medtronic), Cetus (Johnson & Johnson), and NEUWAVE Flex Microwave Ablation System (Johnson and Johnson), FDA product code: NEY.

MWA was first used percutaneously as an adjunct to liver biopsy. It has since been investigated for its efficacy in the treatment of hepatocellular carcinoma, breast cancer, colorectal cancer metastatic to the liver, renal cell carcinoma, renal hamartoma, adrenal malignant carcinoma, non-small cell lung cancer, intrahepatic primary cholangiocarcinoma, secondary splenomegaly and hypersplenism, abdominal tumors and other tumors not amenable to resection. It is also being assessed to determine whether it can reduce the incidence of tumor progression while awaiting transplantation to maintain an individual's ability to meet transplant criteria.

SUPPORTIVE LITERATURE

Uterine Fibroids

RFA was FDA approved as a treatment for symptomatic myomas in 2012 and has been shown to

reduce heavy menstrual bleeding, pelvic pain, and other associated symptoms. The RFA system Acessa for uterine fibroids received FDA clearance for marketing in 2012 (K121858). The device is indicated for use in percutaneous, laparoscopic coagulation and ablation of soft tissue, including treatment of symptomatic uterine fibroids under laparoscopic ultrasound guidance. The next generation of the Acessa System, The Acessa ProVu System, received FDA clearance in 2018. It is indicated for use in percutaneous, laparoscopic coagulation and ablation of soft tissue, including treatment of symptomatic uterine fibroids under laparoscopic ultrasound guidance. In the Acessa procedure, a controlled volume of heat is applied directly to the fibroid, killing the tissue of the fibroid while leaving healthy surrounding tissue unharmed. The dead tissue is reabsorbed by the body.

Rattray et al (2018) published the results of the TRUST Canada study, reporting on the clinical outcomes of pre-and post-laparoscopic RFA for 45 individuals who were greater than 18 years of age, premenopausal, with symptomatic uterine fibroids less than 10 cm in size, a uterine size less than or equal to 16 gestational weeks, a desire for uterine conservation, and were not pregnant or lactating. RFA was compared to individuals receiving a myomectomy. The primary endpoint of hospitalization time was 6.7 ± 3.0 hours for the RFA group and 9.9 ± 10.7 hours for the myomectomy group. Intraoperative blood loss was less for RFA subjects at 25.2 ± 21.6 versus 82.4 ± 62.5 mL (p=0.0002) for the myomectomy group. RFA procedures took less time (70.0 versus 86.5 minutes for myomectomy procedures). At 3 months, both cohorts reported the same significant symptom severity reduction (-44.8%; P<0.0001). RFA subjects took lesser time from work: 11.1 ± 7.6 versus 18.5 ± 10.6 days (P=0.0193). One myomectomy subject was hospitalized overnight after experiencing a 20-second asystole during the procedure. One RFA subject underwent reintervention. The combined per patient direct and indirect costs of the two procedures were comparable.

The TRUST United States trial had a preliminary analysis with a planned follow-up of 5 years conducted by Yu and associates (2022). The RCT will compare laparoscopic RFA or myomectomy in patients with uterine myoma. Inclusion criteria were the same as the TRUST Canada trial. The study evaluates 29 patients who underwent laparoscopic RFA and 27 patients who underwent myomectomy. Primary outcome was again hospital stay, which was significantly shorter in the laparoscopic RFA group (8.01 ± 5.7 hours) than the myomectomy group (18.8 ± 14.6 hours; P<.05). Outcomes of interest for the primary analysis were symptoms and patient reported quality of life at 12 months. Symptoms improved in both groups at both 3 and 12 months with no statistical difference between the two. Symptom severity and health-related quality of life were significantly better in the myomectomy group at 12 months. Major complications occurred in 2 patients in the myomectomy group and 1 patient who had RFA. The study was limited by its lack of blinding, to both the treatment and treating physician.

Miller and colleagues (2019) investigated the Sonata device for the treatment of symptomatic uterine fibroids with 2-year outcomes. This prospective multicenter single-arm interventional trial included premenopausal women with up to 10 clinically relevant uterine fibroids ranging from 1 to 5 cm in diameter. The individuals were treated with sonography-guided transcervical fibroid ablation (TFA) and were assessed for symptom severity, health related quality of life, general health status, work and activity limitations, treatment satisfaction, adverse events, surgical reintervention, and occurrence of pregnancy and associated outcomes. Of the 147 women who were enrolled, 85%

(125/147) returned for 2-year follow up. Symptom severity decreased from 55 ± 19 to 24 ± 18 (P < 0.001), health-related quality of life increased from 40 ± 21 to 83 ± 19 (P < 0.001). Overall treatment satisfaction at two years was 94%. The mean percentage of missed work time, overall work impairment, and activity impairment significantly decreased at follow-up. Through two years, surgical reintervention for heavy menstrual bleeding was performed in 5.5% of patients. One singleton pregnancy occurred with a normal peripartum outcome. The authors concluded that treatment with the Sonata system provides a significant clinical improvement through two years post-ablation.

Renal Tumors

Renal ablation traditionally has been reserved for patients who are poor candidates for surgery or in whom renal preservation is of utmost priority. However, with some reports on oncologic efficacy approaching that of partial nephrectomy (PN), renal ablation can be considered as a first-line treatment option for patients who meet specific criteria.

Yanagisawa et al (2022) published a systematic review and meta-analysis comparing ablative therapies (cryoablation, radiofrequency ablation, and microwave ablation) to partial nephrectomy. Twenty-seven trials (N=13,996) were included; 12 of those studies directly compared cryoablation with partial nephrectomy, however, the results were not stratified by modality. No significant differences in cancer-specific mortality for cT1a tumors (p=.50) and cT1b tumors (p=.63) were found when comparing partial nephrectomy and ablation therapies. Local recurrence was higher for ablative therapies compared with partial nephrectomy in both cT1a tumors (risk ratio, 0.43; 95% confidence interval [CI], 0.28 to 03.66; p=.0001) and cT1b tumors (risk ratio, 0.41; 95% CI, 0.23 to 0.75; p=.004). There were no significant differences between partial nephrectomy and ablation therapy in terms of rate of metastases, overall complications, and decline in renal function.

Lim et al (2020) completed a study to evaluate the immediate and 3- and 5-year outcomes of patients with clinical stage T1 (cT1) biopsy-proven RCC who were treated by percutaneous cryoablation. A total of 180 patients with 185 separate cT1 RCC lesions were identified. Mean patient age was 68.4 years (range, 34.1 – 88.9 years) and 52 patients (28.9%) were women. There were 168 (90.8%) and 17 (9.2%) cT1a and cT1b lesions, respectively, with a mean lesion size of 28.5 mm (range, 11 – 58 mm). Technical success was achieved in 98.9% of patients. The major complication rate was 2.2%. Residual unablated tumor on the first follow-up scan was identified in four of 183 tumors (2.2%). Estimated local tumor progression-free survival at 3 and 5 years was 98.3% and 94.9%, respectively. No distant metastases or deaths attributable to RCC occurred. Mean estimated glomerular filtration rate before the procedure was 72.4 ± 18.5 (SD) mL/min/1.73 m2 and this was not statistically significantly different after the procedure (69.7 ± 18.8 mL/min/1.73 m2), at 1 year (70.7 ± 16.4 mL/min/1.73 m2), or at 2 years (69.8 ± 18.9 mL/min/1.73 m2 (p> 0.05). The authors concluded that this data adds to the accumulating evidence that image-guided cryoablation is an efficacious treatment for selected cT1 RCC with a low complication rate and robust 3- and 5-year outcomes.

McClure et al (2023) conducted a systematic review and meta-analysis comparing microwave ablation and cryoablation for renal cell carcinoma. Study arms from RCTs, comparative observational, and

single-arm studies were eligible. The outcomes included local tumor recurrence (LTR), overall survival, disease-free survival, overall/major complications, procedure/ablation time, 1- to 3-month primary technique efficacy, and technical success. Baseline characteristics were similar between groups and mean tumor size for MWA and cryoablation were 2.74 and 2.69 cm. Single-arm meta-analyses were similar for LTR and secondary outcomes between cryoablation and MWA. Ablation time was significantly shorter with MWA than with cryoablation (meta-regression weighted mean difference 24.55 minutes, 95% confidence interval -31.71, -17.38, P < .0001). One-year LTR was significantly lower with MWA than cryoablation (odds ratio 0.33, 95% confidence interval 0.10-0.93, P = .04). There were no significant differences for other outcomes. MWA provides significantly improved 1-year LTR and ablation time compared with cryoablation for patients with RCC. Other outcomes appeared similar or favorable for MWA; however, results were not statistically significant. MWA of primary RCC is as safe and effective as cryoablation, which should be confirmed with future comparative studies.

Liver Tumors

The evidence supporting the use of RFA in the treatment of inoperable hepatic metastases includes an RCT, systematic reviews and meta-analyses, prospective cohort series, and retrospective case series. There are no RCTs comparing RFA with alternative treatments for patients who have unresectable colorectal liver metastases. However, an RCT assessing RFA plus chemotherapy found improved survival at eight (8) years compared with chemotherapy alone. In addition, prospective studies have demonstrated that overall survival following RFA is at least equivalent to and likely better than currently accepted systemic chemotherapy in well-matched patients with unresectable hepatic metastatic colorectal cancer (CRC) who do not have extrahepatic disease. Results from a number of uncontrolled case series also have suggested RFA of hepatic CRC metastases produces long-term survival that is at a minimum equivalent to but likely superior to historical outcomes achieved with systemic chemotherapy. Evidence from a comparative study has indicated RFA has fewer deleterious effects on quality of life than chemotherapy and that RFA patients recover their quality of life significantly faster than chemotherapy recipients. It should be noted that patients treated with RFA in different series might have had better prognoses than those who had chemotherapy, suggesting patient selection bias might at least partially explain the better outcomes observed following RFA. The evidence is sufficient to determine that the technology results in an improvement in the net health outcome.

Mohan et al (2015) published a systematic review of RFA as a treatment for unresectable metastases from neuroendocrine tumors. Seven unique studies (N=301 patients), all retrospective case series from a single institution, were included. The most common tumor type was carcinoid (59%), followed by nonfunctional pancreatic tumors (21%) and functional pancreatic tumors (13%). There were 2 periprocedural deaths (rate, 0.7%), and the overall complication rate was 10%, including hemorrhage, abscess, viscus perforation, bile leak, biliopleural fistula, transient liver insufficiency, pneumothorax, grounding pad burn, urinary retention, pneumonia, and pleural effusion. Improvement in symptoms was reported in 92% (117/127) of symptomatic patients, with a median duration of relief ranging from 14 to 27 months. There was a high degree of variability in the length of follow-up and surveillance, and a wide range of local recurrence rates, from less than 5% to 50%;

5-year survival rates ranged from 57% to 80%.

Fairweather et al (2017) compared the overall survival in patients with neuroendocrine liver metastases (N=649) from a large prospective database. Primary treatment modalities included: systemic therapy (n=316), chemoembolization (n=130), observation (n=117), surgical resection (n=58), and RFA (n=28). The most favorable 10-year overall survival estimates were achieved with surgical resection (70%), followed by RFA (55%), systemic therapy (31%), chemoembolization (28%), and observation (20%).

Most reports of RFA treatment for neuroendocrine liver metastases have assessed small numbers of patients or subsets of patients in reports of multiple ablative methods or small subsets of larger case series of patients with various diagnoses. The available evidence has indicated that durable tumor and symptom control of neuroendocrine liver metastases can be achieved using RFA in individuals whose symptoms are not controlled by systemic therapy or who are ineligible for resection.

For individuals who have hepatic metastases, not of colorectal or neuroendocrine origin who receive RFA, the evidence includes a systematic review, small, nonrandomized comparative studies and small case series. Relevant outcomes are overall-survival, disease-specific survival, symptoms, change in disease status, morbid events, quality of life, and treatment-related morbidity. For patients who are ineligible for resection, RFA may provide a survival benefit. However, the evidence is limited by study designs with a high-risk of bias and small sample sizes. The evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

Glassberg et al (2019) conducted a systematic review and meta-analysis of 16 trials comparing MWA to resection in adults with confirmed HCC or liver cancer. The review included 1 RCT and 15 observational studies (two prospective and 13 retrospective). The studies represented 965 individuals treated with MWA and 755 resections from a period of 15 months to 5 years. Patients who received MWA had a significantly higher risk of local tumor progression compared to those who received resection. At 1-year, overall survival did not differ between MWA and resection but 3- and 5-year overall survival was significantly higher in patients who had received resection. Complications were lower with MWA compared to resection. Additionally, operative time, intraoperative blood loss, and hospital length of stay were significantly lower with MWA. Some studies included patients that were nonresectable in the MWA treatment arm, but due to limited reporting and patient preference affecting which treatment was performed, the reviewers were not able to calculate the number of patients who were nonresectable or to conduct subgroup analyses by resectable versus unresectable tumors. Microwave ablation was typically selected for patients with smaller and/or deeper tumors, more comorbidities, and a preference for a less invasive procedure. The reviewers concluded that MWA can be an effective and safe alternative to hepatic resection in patients or tumors that are not amenable to resection, but more studies are needed to determine the target population that would benefit most from MWA.

Chong and colleagues (2020) conducted an RCT of 93 patients with HCC who had up to three lesions of 5 cm or smaller, Child-Pugh score A or B, the absence of extrahepatic metastases, and absence of radiologic evidence of major vascular or bile duct invasion. The primary outcome of the study was rate of complete ablation at 1 month, which did not differ significantly for MWA. Rates of overall

survival up to 5 years and rates of disease-free survival up to 3 years were similar between groups. Limitations of the study included that sample size calculations were based on complete ablation at one month, so the study may not have been adequately powered to detect differences in the overall survival or disease-free survival.

The body of evidence indicates that MWA is an effective option in patients for whom resection is not an option. Although studies have methodological limitations, they consistently showed that MWA and RFA had similar outcomes with up to 5 years of follow-up in patients with a single tumor ≤ 5cm or up to three nodules ≤ 3 cm each.

Bridge to Liver Transplant

The Milan criteria are used to identify the tumor burden of patients with hepatocellular carcinoma (HCC) as smaller tumors are more likely to allow for a good outcome after liver transplantation. The Milan criteria state that transplantation should be performed in those with a single tumor of 5 cm or less or three (3) tumors that are each 3 cm or less, with no macrovascular invasion, and no metastasis. Patients who do not meet the Milan criteria are not considered eligible candidates for liver transplantation.

The dropout rates of patients with HCC from liver transplant lists have been reported to range from 20-40% due to tumor progression. Recent studies utilizing RFA as a bridge to transplant have increased days on the transplant list considerably and decreased dropout rates to 12-15%.

The evidence related to the use of RFA specifically to downsize/downgrade tumors to meet priority transplant criteria is insufficient at this time due to inconsistent outcomes reported in the literature. Studies regarding tumor recurrence in this patient population demonstrate a longer-term follow-up are needed.

Bone Tumors

The majority of literature on the use of RFA on patients with bone metastases consists of uncontrolled studies with only a limited number of cases. However, the patient populations enrolled in the studies comprised individuals with limited or no treatment options, for whom short-term pain relief was an appropriate outcome.

Studies investigating the efficacy of RFA for osteoid osteomas provide evidence that RFA achieves outcomes comparable to surgical excision, in terms of tumor destruction and pain relief, and allows for a decrease in hospital stay and quicker postoperative recovery. RFA treatment of osteoid osteoma is not appropriate for large lesions or for those in a location that makes it technically difficult to perform percutaneously.

Jennings et al (2021) reported on a single-arm prospective study of 66 patients with metastatic bone disease who were treated with cryoablation and were not candidates for or had not benefitted from standard therapy. The primary endpoint was the change in pain score from baseline to week 8 and patients were followed for 24 weeks. The mean decrease in pain score from baseline to week 8 was 2.61 points (95% CI, 3.45 to 1.78). Pain scores decreased further after the primary endpoint and reached clinically meaningful levels (more than a 2-point decrease) after week 8. This study had

several limitations, including the lack of a comparator, potential for selection bias, and lack of blinding combined with subjective outcome measures.

Khanmohammadi et al (2023) conducted a systematic review to understand the safety and effects of cryoablation on the pain and quality of life (QoL) of patients with bone metastasis. Inclusion criteria were original studies published until September 8, 2022, studies on patients 18 years and affected by bone metastasis, bone metastasis treated with stand-alone cryoablation, studies reporting patients' pain before and at least one time-point following cryoablation and English language studies. Fifteen studies on 376 patients were included. All studies reported a significant pain reduction between one day and six months after the cryoablation procedure. The highest mean difference between pre- and post-procedure scores was 5.8 (VAS scale) after four weeks. The overall rate of minor and major complications was 12.74%. Cryoablation improved the QoL of cancer patients and decreased the need for analgesics. Authors concluded that cryoablation is a safe and useful procedure for palliating painful bone metastasis and increasing the QoL of cancer patients. Future studies should adopt a standardized pain reporting scale to allow for meta-analysis.

Bianchi et al (2022) conducted a review of current literature and concluded that percutaneous thermal ablation techniques are a safe and effective therapeutic option in the treatment of osteoid osteomas (OO). Among the currently available ablation techniques, RFA is considered the gold standard due to the possibility to perform a preliminary biopsy, whose utility is however still controversial. RFA and cryoablation (CA) have statistically similar outcomes in terms of technical success, clinical efficacy, and low recurrence and complications rate. CA is the only technique allowing real-time visualization of the ablated volume (ice ball sign), which maximizes treatment safety. Furthermore, CA shows promising results in patients submitted to treatment of bone metastases in terms of better medical therapy management, pain relief, and subsequent improvement of life quality. CA brings lower risks of permanent nerve damage when the lesions are located near neural structures. There is even evidence of nerve regeneration after damage caused by cryoablation.

Le Corroller et al (2022) conducted a retrospective single-center study that evaluated 50 consecutive patients with osteoid osteoma treated with CT-guided percutaneous cryoablation. Technical success was achieved in all procedures, and overall clinical success was 96% (48/50 patients). The median VAS pain score was 8 (IQR, 7–8) before the procedure and 0 (IQR, 0–1; P , .001) after the procedure at both primary (6 weeks) and secondary (18–90 months) follow-up. Only one recurrence was reported and was successfully retreated with CA. Authors concluded that CT-guided percutaneous cryoablation has a favorable safety profile with few complications, demonstrated high clinical success and was frequently performed under local anesthesia with conscious sedation.

Lung Tumors

Cryosurgical ablation for the treatment of NSCLC has been studied in a limited number of small studies. Moore, et al (2015) conducted a case series involving 47 subjects with NSCLC. The subjects were followed for a minimum of 5 years after treatment with cryoablation. The authors reported that the five-year survival rate was 67.8% ± 15.3, the cancer-specific survival rate at five years was 56.6% ± 16.5, and the five-year progression-free survival rate was 87.9%. The combined local and

regional recurrence rate was 36.2%. Major complications were reported in 6.4% of subjects, with two cases of hemoptysis and a prolonged placement of a chest tube requiring mechanical sclerosis in one subject. No deaths occurred in the first 30 days after treatment.

A prospective case series conducted by deBaere et al (2015), assessed 40 patients with 60 treated metastatic lung tumors (3.5cm or less in diameter) from a variety of primary origin. The most common origin was colorectal cancer (40%). Follow-up to 12 months was reported, involving 35 patients (90%). At 12 months, overall local tumor control, including stable disease, partial response, and complete response, was seen in 49 of 52 metastases (94.2%) and 32 of 35 patients (91.4%). Local failure was observed in three of 52 metastases (5.8%) at 6 and 12 months with increasing size of the ablation zone. Tumor diameter was not found to be a significant factor in the rate of tumor progression (p=0.41). Additional new treatments were administered to 15 of the 40 patients (38%) including systemic treatment (chemotherapy: n=7 and immunotherapy: n=1) and other focal therapies for new metastatic disease (n=10), including 6 cryoablation procedures. One-year disease-specific survival and overall survival rates were 100% and 97.5% respectively. Pneumothorax requiring chest tube placement occurred in nine of the 48 procedures (18.8%), and chest tubes were removed after one day (n=8) or two days (n=1). Common Terminology Criteria for Adverse Events (CTCAE) grade 3 adverse events within 30 days of the procedure occurred in three of 48 (6%) procedures including a delayed pneumothorax requiring pleurodesis, a thrombosis of a pre-existing hemodialysis access arterio-venous fistula requiring thrombectomy, and a non-cardiac chest pain that spontaneously resolved. No grade 4 or 5 procedure-related adverse events occurred. No procedural-related delayed adverse events were observed. The study outcomes were considered interim results at 1-year follow up.

In 2021, deBaere et al published follow-up 5- year results in a prospective, multicenter, single arm study of the 40 patients from the original 2015 study, using a standardized CA protocol (ECLIPSE). The primary end point was local tumor control both per tumor and per patient. Local failure was defined as a greater than 20% increase in diameter of the ablation zone from baseline imaging. Secondary end points included cancer-specific survival, overall survival, and quality of life. The local tumor control rates per index tumor were 87.9% at 3 years and 79.2% at 5 years; the 5-year overall survival was 46.7% with 78.2% of surviving patients without progression. Five treated patients experienced local progression throughout the duration of the study, with a local control rate of treated tumors of 75.0% per patient and 79.2% per tumor when treating lung metastases up to 3.5 cm. The authors concluded that these results indicate that the rates of local tumor control, recurrence, and progression in 5 years of follow-up were similar to or better than those of the studies of each type of treatment modality previously described. Although the quality-of-life data did not reach significance, the authors concluded that CA is an effective means of local tumor control in patients with metastatic lung disease.

In 2020, Callstrom et al assessed the safety and local recurrence-free survival after cryoablation for the treatment of pulmonary metastases in a multicenter, single-arm, phase II study in 128 patients with 224 lung metastases ≤3.5 cm (SOLSTICE). The median tumor size was 1.0 cm. Local recurrence-free response was 85.1% at 12 months and 77.2% at 24 months. Secondary local recurrence-free response after re-treatment with cryoablation for recurrent tumors was 91.1% at 12

months and 84.4% at 24 months. Overall survival at 12 and 24 months was 97.6% and 86.6%, respectively.

For individuals who have an unresectable primary or metastatic lung tumor who receive MWA, the evidence includes a single RCT, retrospective observational studies, and systematic reviews of these studies. The RCT by Macchi et al (2017) MWA compared to RFA for lung tumors in 52 patients with a single tumor up to 5 cm, and up to 5 metastases up to 5 cm in size. However, at baseline, the mean tumor size was 2.21 cm (standard deviation [SD], 0.89) in the MWA group and 1.64 cm (SD, 0.80) in the RFA group. Mortality rates at 6 and 12 months did not differ between groups, and complications were significantly lower in the MWA group. Limitations of this study include its small sample size, lack of reporting on blinding, and relatively short follow-up period (12 months). Results were not reported by tumor size or the number of metastases. Systematic reviews determined that local recurrence rates for MWA and RFA were similar at a range of 9 to 47 months of follow-up. Authors conclude that RFA and MWA were both effective with a high safety profile. Limitations exist within the body of evidence include lack of controlled studies and heterogeneity across studies. The studies did not report enough information to assess the effectiveness or safety of MWA in subgroups based on the presence of multiple tumors or total tumor burden. Therefore, conclusions cannot be drawn about the comparable effectiveness of MWA in patients that have more than one tumor.

Murphy et al (2023) conducted a bi-institutional retrospective cohort study to evaluate the safety and effectiveness of percutaneous imagine-guided thermal ablation (IGTA) for juxtacardiac lung tumors. The study included 23 consecutive patients with 30 juxtacardiac lung tumors located less than or equal to ten millimeters from the pericardium treated in 28 IGTA sessions (25 sessions of cryoablation and three sessions of microwave ablation). The primary outcome was any adverse cardiac event within 90 days after ablation. Secondary outcomes included noncardiac adverse events, local tumor progression–free survival (LT-PFS), and the cumulative incidence of local tumor progression with death as a competing risk. The median imaging follow-up duration was 22 months. Primary technical success was achieved in 25 (89%) ablations. No adverse cardiac events attributable to IGTA occurred. One patient experienced a phrenic nerve injury. The median LT-PFS duration was 59 months. At one, three, and five years, LT-PFS was 90% (95% CI, 78%–100%), 74% (CI, 53% – 100%), and 45% (CI, 20% – 97%), respectively, and the cumulative incidence of local tumor progression was 4.3% (CI, 0.29% – 19%), 11% (CI, 1.6% – 30%), and 26% (CI, 3.3% – 58%), respectively.

Breast Tumors

The available literature on the use of cryosurgery in the treatment of breast cancer has shown that complete ablation can be achieved in most cases for variably defined small tumors, but studies have not included control groups or compared outcomes of cryosurgery with alternative strategies for managing similar patients. Therefore, no conclusions can be made on the net health outcome of cryosurgery for breast cancer. For the treatment of fibroadenomas, there is a small body of evidence. This evidence has demonstrated that most fibroadenomas become "nonpalpable" following cryoablation. However, there is a lack of comparative trials. Comparative trials are needed to assess this technology and determine how this approach compares with standard treatments.

Pancreatic Tumors

The available evidence on cryosurgery for pancreatic cancer consists of retrospective case series that used cryosurgery for palliation of inoperable disease and a systematic review of these studies. These studies reported that pain relief was achieved in most cases and that complications such as delayed gastric emptying, are common but the true rate of complications is uncertain. Because these studies did not include control groups or compare outcomes of cryosurgery with alternative strategies for managing similar patients, no conclusions can be made on the net health outcome of cryosurgery for pancreatic cancer.

Desmoid Tumors

In a 2024 update to the global evidence-based consensus guidelines for desmoid tumor management, Kasper et al introduced significant changes reflecting current clinical practices. Notably, cryoablation is now recognized as a valid local therapy option, especially for patients with inoperable, symptomatic, or progressive tumors where systemic therapy is not preferred. The guidelines emphasize the importance of multidisciplinary care and recommend treatment at specialized centers to ensure optimal outcomes. Additionally, the update marks a shift away from surgery as the default first-line treatment, favoring more conservative and individualized approaches that prioritize patient quality of life.

Tremblay et al (2019) conducted a retrospective review of 23 patients treated with CT-guided cryoablation between 2014 and 2018. These patients, aged 16 to 77, had extra-abdominal desmoid tumors and underwent a total of 30 cryoablation sessions, either as first-line (61%) or salvage therapy (39%). The study found that cryoablation achieved technical success in all cases, with a median follow-up of 15.4 months. Symptomatic improvement was reported in 89% of patients, and imaging showed an average 80% reduction in viable tumor volume at 12 months. Tumor response rates included 36% complete response, 36% partial response, and 28% stable disease, with no cases of rapid post-ablation growth or track seeding. Although two patients experienced significant neuropraxia, overall morbidity was low. The authors concluded that cryoablation is a safe and effective treatment option for extra-abdominal desmoid tumors, offering strong symptom relief and local control with minimal complications.

The CRYODESMO-01 study, a prospective, open-label phase II trial led by Kurtz et al (2020), evaluated cryoablation in patients with desmoid tumors that had progressed after prior medical therapy. The study enrolled 45 patients across multiple centers, all of whom had symptomatic or progressive disease and were not candidates for surgery. Cryoablation achieved a 12-month local control rate of 86.7%, with 71.1% of patients experiencing a partial response and 24.4% achieving stable disease. Importantly, 91% of patients reported symptom improvement, particularly in pain and functional limitations. Adverse events were mostly mild to moderate, with no treatment-related deaths. These results support cryoablation as a safe and effective local therapy for select desmoid tumor patients, especially when systemic options are limited or not preferred.

Schmitz et al (2016) reviewed outcomes from a decade of treating patients with extra-abdominal desmoid tumors using CT-guided cryoablation. The retrospective analysis included 23 patients who underwent a total of 30 cryoablation procedures. The study reported a 100% technical success rate,

with 89% of patients experiencing symptomatic improvement, particularly in pain and mobility. Imaging follow-up showed an average 80% reduction in viable tumor volume at 12 months. Tumor response rates included 36% complete response, 36% partial response, and 28% stable disease, with no cases of rapid post-ablation growth or track seeding. Authors concluded that this analysis supports cryoablation as a safe and effective treatment option for extra-abdominal desmoid tumors.

Other Solid Tumors

The evidence on the use of RFA for malignant solid tumors other than liver, consist of case studies, which have reported only short-term outcomes such as tumor response and immediate tumor control. These studies have not determined RFA's effect on the overall survival and net health benefit of these patients compared to the well-established local and systemic treatments currently available for these tumors. More rigorous scientific reviews, long-term follow-up and randomized prospective trials are needed to help better define the role of RFA in the treatment of other solid tumors.

The current evidence on cryoablation for all other indications consists largely of non-comparative, case series and is insufficient to permit conclusions concerning the effect of cryoablation on health outcomes. The outcomes of these case series are inconclusive due to heterogeneity of the patient populations studied and to the lack of long-term data on the effectiveness of cryosurgical ablation on overall survival. Most case series report only short-term outcomes such as tumor response in terms of shrinkage and tumor recurrence. Comparative studies with already established treatments, larger numbers of subjects, and longer follow-up are needed.

There are well-established local or systemic treatment options available for each of the malignancies in which MWA has been investigated. Potential advantages of MWA include improved local control and the minimally invasive nature of the modality to preserve normal organ tissue, decrease morbidity, and shorten the length of hospitalization, however there is insufficient evidence and a need for further studies to confirm that MWA does indeed improve health outcomes over other standard treatments in indications other than hepatic and lung tumors.

PROFESSIONAL GUIDELINE(S)

The American College of Gynecology (ACOG) released an updated practice bulletin in mid-2021 stating that laparoscopic RFA can be considered as a minimally invasive treatment option for the management of symptomatic leiomyomas in patients who desire uterine preservation and are counseled about the limited available data on reproductive outcomes.

The American Association of Gynecologic Laparoscopists (AAGL) (2022) commented that current review of the literature suggests RFA offers a safe and effective alternative treatment option for patients with symptomatic fibroids who seek uterine preservation. Although RFA is not yet approved by the FDA as a fertility-enabling treatment, subsequent successful pregnancy outcomes have been reported in the literature. More robust fertility data is required to confirm its safety for those who actively desire future pregnancy.

The Society of Interventional Radiology (2020) published a position statement on the role of percutaneous ablation in renal cell carcinoma. Their relevant recommendations are as follows:

- "In patients with small renal tumors (stage T1a), percutaneous thermal ablation is a safe and effective treatment with fewer complications than nephrectomy and acceptable long-term oncological and survival outcomes. (Level of Evidence: C; Strength of Recommendation: Moderate)"
- "In selected patients with suspected T1a renal cell carcinoma, percutaneous thermal ablation should be offered overactive surveillance. (Level of Evidence: C; Strength of Recommendation: Moderate)"
- "In high-risk patients with T1b renal cell carcinoma who are not surgical candidates, percutaneous thermal ablation may be an appropriate treatment option; however, further research in this area is required. (Level of Evidence: D; Strength of Recommendation: Weak)"
- "Radiofrequency ablation, cryoablation, and microwave ablation are all appropriate modalities for thermal ablation, and method of ablation should be left to the discretion of the operating physician. (Level of Evidence: D; Strength of Recommendation: Weak)"

The 2021 American Urological Association guidelines on Stage I renal masses indicate that cryoablation may be offered as an option for the management of cT1a solid renal masses < 3 cm in size, with the percutaneous technique being preferred over a surgical approach wherever feasible to minimize morbidity (Moderate Recommendation; Evidence Level: Grade C). Counseling about thermal ablation should include information regarding an increased likelihood of tumor persistence or local recurrence after primary thermal ablation relative to surgical excision, which may be addressed with repeat ablation if further intervention is elected. (Strong Recommendation; Evidence Level: Grade B).

The American College of Radiology Appropriateness Criteria (2009, updated 2021) for post-treatment follow-up and active surveillance of renal cell carcinoma (RCC) indicates that "ablative therapies, such as radiofrequency ablation, microwave ablation, and cryoablation, have been shown to be effective and safe alternatives (to surgical resection) for the treatment of small, localized RCCs.

In 2018, The American Association for the study of Liver Disease released guidelines for the diagnosis, staging and management of HCC. The guidelines suggest that patients who do not meet Milan criteria can be treated with ablative therapy to induce tumor death and deter tumor progression beyond the Milan criteria. In regard to the criteria, the association states, "Thermal ablation is superior to ethanol injection. Thermal ablative techniques have the best efficacy in tumors with maximum diameter less than 3 cm, although microwave ablation potentially provides better tumoral response than RFA. Patients that are post-ablation are at high risk for recurrence and surveillance should be performed with contrast-enhanced CT or MRI every 3-6 months".

NCCN Guidelines for NSCLC (V.6.2026) notes that the use of image-guided thermal ablation (IGTA), which includes radiofrequency ablation, microwave ablation, and cryoablation, may be a treatment option for NSCLC. IGTA may be an option for select patients who are deemed "high risk"-those patients with tumors that are for the most part surgically resectable but rendered medically inoperable due to comorbidities. IGTA has been successfully accomplished in patients considered "high risk," objectively defined with a single major and/or two or more minor criteria. Major criteria for high risk included an FEV1 or DCLO ≤ 50 percent and minor criteria included less depressed FEV1

or DCLO between 51-60 percent, advanced age ≥ 75 years, pulmonary hypertension, VEF ≤ 40 percent, resting or exercise paO2 <55mmHg, and PCO2>45 mmHg.

The NCCN guidelines (V.1.2027) for kidney cancer indicate that thermal ablation (eg, cryosurgery, radiofrequency ablation, microwave ablation) is an option for the management of clinical stage T1 renal lesions. Thermal ablation is an option for clinical T1b masses in select patients not eligible for surgery. Biopsy of lesions is recommended to be done prior to or at time of ablation. Ablative techniques may require multiple treatments to achieve the same oncologic outcomes as conventional surgery.

The NCCN guidelines for soft tissue sarcoma (V.4.2026) recognizes cryoablation as the recommended ablation modality for desmoid tumors.

REGULATORY STATUS

The U.S. Food and Drug Administration (FDA) has cleared hundreds of RFA devices for the general indication of soft tissue cutting, coagulation, and ablation by thermal coagulation necrosis. Under this general indication, RFA can be used to ablate tumors. Some RFA devices have been cleared for additional specific treatment indications, including partial or complete ablation of nonresectable liver lesions and palliation of pain associated with metastatic lesions involving bone. FDA product code: GEI.

The Sonata Sonography-Guided Transcervical Fibroid Ablation System (Gynesonics) received FDA clearance for marketing in 2018. This device is intended for diagnostic intrauterine imaging and transcervical treatment of symptomatic uterine fibroids, including those associated with heavy menstrual bleeding.

The RFA system Acessa for uterine fibroids, received FDA clearance for marketing in 2012 (K121858). The next generation of the Acessa System, The Acessa ProVu System, received FDA clearance in 2018.

The United States Food and Drug Administration (FDA) regulates medical devices. All thermal ablation related devicesincluding related components require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2026 Jul 10]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most serious type of recalls. Available from: Medical Device Recalls | FDA [accessed 2026 Jul 10]

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
19105 (E/I)	Ablation, cryosurgical, of fibroadenoma, including ultrasound guidance, each fibroadenoma
20982	Ablation therapy for reduction or eradiation of one or more bone tumors (e.g., metastasis) including adjacent soft tissue when involved by tumor extension, percutaneous, including imaging guidance when performed; radiofrequency
20983 (E/I)	Ablation therapy for reduction or eradication of 1 or more bone tumors (e.g., metastasis) including adjacent soft tissue when involved by tumor extension, percutaneous, including imaging guidance when performed; cryoablation
32994	Ablation therapy for reduction or eradication of 1 or more pulmonary tumor(s) including pleura or chest wall when involved by tumor extension, percutaneous, including imaging guidance when performed, unilateral; cryoablation
32998	Ablation therapy for reduction or eradication of one or more pulmonary tumor(s) including pleura or chest wall when involved by tumor extension, percutaneous, including imaging guidance when performed, radiofrequency, unilateral
47370	Laparoscopy, surgical, ablation of one or more liver tumor(s); radiofrequency
47371 (E/I)	Laparoscopy, surgical ablation of one or more liver tumor(s); cryosurgical
47380	Ablation, open, of one or more liver tumor(s); radiofrequency
47381 (E/I)	Ablation, open, of one or more liver tumor(s); cryosurgical
47382 (*E/I)	Ablation, one or more liver tumor(s), percutaneous, radiofrequency (*E/I when utilized for Cryosurgical Ablation)
47383 (E/I)	Ablation, 1 or more liver tumor(s), percutaneous, cryoablation
50250	Ablation, open, one or more renal mass lesion(s), cryosurgical, including intraoperative ultrasound guidance and monitoring, if performed
50542	Laparoscopy, surgical; ablation of renal mass lesion(s), including intraoperative ultrasound guidance and monitoring, when performed
50592	Ablation, one or more renal tumor(s), percutaneous, unilateral, radiofrequency
50593	Ablation, renal tumor(s), unilateral, percutaneous, cryotherapy
58674 (*E/I)	Laparoscopy, surgical, ablation of uterine fibroid(s), including intraoperative ultrasound guidance and monitoring, radiofrequency (*E/I when utilized for Microwave Ablation)

Code	Description
60660 (E/I)	Ablation of 1 or more thyroid nodule(s), one lobe or the isthmus, percutaneous, including imaging guidance, radiofrequency
60661 (E/I)	Ablation of 1 or more thyroid nodule(s), additional lobe, percutaneous, including imaging guidance, radiofrequency (List separately in addition to code for primary procedure) (
60699 (*E/I)	Unlisted procedure, endocrine system (*E/I when used for adrenal or thyroid ablation [RF, CA, or MWA])
76940 (*E/I)	Ultrasound guidance for, and monitoring of, parenchymal tissue ablation (*E/I when utilized for Microwave Ablation)
77013	Computed tomography guidance for, and monitoring of, parenchymal tissue ablation
77022	Magnetic resonance imaging guidance for, and monitoring of, parenchymal tissue ablation
0581T (E/I)	Ablation, malignant breast tumor(s), percutaneous, cryotherapy, including imaging guidance when performed, unilateral
58580 (*E/I)	Transcervical ablation of uterine fibroid(s), including intraoperative ultrasound guidance and monitoring, radiofrequency (*E/I when utilized for CA or MWA)

MEDICAL POLICY

Medical Policy Title	**Tibial Nerve Stimulation (TNS) for Voiding Dysfunction**
Policy Number	**8.01.22**
Current Effective Date	**January 1, 2027**
Next Review Date	**April 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service.
(Link to Product Disclaimer)

Transcutaneous Posterior Tibial Nerve Stimulation is not addressed in this policy.

POLICY STATEMENT(S)

I. Percutaneous posterior tibial nerve stimulation (PPTNS) is considered **medically appropriate** as a treatment modality for patients with urinary urge incontinence, nonobstructive urinary retention, or overactive bladder (OAB) symptoms who meet **BOTH** of the following criteria:

   A. Failure of conservative behavioral therapies of at least three (3) months' duration;

   B. Failure of pharmacological therapy **or** patient has a contraindication to pharmacological therapy. For urinary urge incontinence and OAB, that includes at least two (2) anticholinergic or beta-3 adrenergic agonist medications or smooth muscle relaxants.

II. Percutaneous posterior tibial nerve stimulation (PPTNS) is considered **investigational** for all other uses, including, but not limited to, **ALL** of the following:

   A. Voiding dysfunction due to a neurological condition;

   B. Constipation;

   C. Fecal incontinence (FI).

III. An implanted TNS is considered **investigational** for all indications.

RELATED POLICIES

Corporate Medical Policy

1.01.19 Pelvic Floor Electrical Stimulation as a Treatment for Urinary or Fecal Incontinence

1.01.55 Electrical Stimulation as a Treatment for Pain and Other Medical Conditions

7.01.10 Sacral Nerve Stimulation

11.01.03 Experimental or Investigational Services

POLICY GUIDELINE(S)

I. Twelve weekly office visits for PPTNS treatment sessions are considered the standard treatment plan. Then, once monthly maintenance therapy will be considered if the patient has exhibited at

least a 50% improvement in voiding symptoms (based on documentation such as patient voiding diaries) after the initial 12 sessions.

II. Maintenance therapy is dependent on documentation of a continued treatment response.

DESCRIPTION

PPTNS is an office-based procedure that utilizes electrical neuromodulation in the treatment of voiding dysfunction in patients who have failed conservative therapies (e.g., behavioral, pharmacological). Voiding dysfunction includes urinary frequency, urgency, incontinence, and nonobstructive retention and is usually initially treated with behavioral interventions and/or medications such as anticholinergics. Behavioral therapies include (but are not limited to) fluid management, bladder training/timed voiding, and physiotherapy.

The procedure for PPTNS consists of the insertion of a needle above the medial malleolus into the posterior tibial nerve, followed by the application of low-voltage (10mA, 1–10 Hz frequency) electrical stimulation that produces sensory and motor responses (e.g., a tickling sensation and plantar flexion or fanning of all toes). The recommended course of treatment is an initial series of 12 weekly, office-based treatments, followed by an individualized maintenance treatment schedule.

While the posterior tibial nerve is located near the ankle, it is derived from the lumbar-sacral nerves (L4-S3), which control the bladder detrusor and perineal floor. Altering the function of the posterior tibial nerve with PPTNS is believed to improve voiding function and control.

PPTNS has also been proposed as treatment for individuals with non-neurogenic and neurogenic bladder syndromes and fecal incontinence.

The eCoin Peripheral Neurostimulator (Valencia Technologies Corporation) is a coin-sized leadless stimulator that is implanted subcutaneously using local anesthetic in the lower leg and delivers 30-minute treatments without the need for users to manipulate to deliver stimulation.

SUPPORTIVE LITERATURE

Randomized Control Trials for PPTNS

Peters and colleagues published an industry sponsored RCT in 2010 (SUmiT trial). The eligibility criteria included a score of at least four on the overactive bladder questionnaire (OAB-q) short form for urgency, self-reported bladder symptoms lasting at least three months, and failure of conservative care. A total of 220 patients were randomized, 110 to the PPTNS group and 110 to the sham group. Both groups received 12 weekly, 30-minute intervention sessions. The 12-week course of treatment was completed by 103 of 110 (94%) in the PPTNS group and 105 of 110 (95%) in the sham group. The primary study outcome was response to treatment based on a single-item global response assessment (GRA). The proportion of patients who responded to treatment based on the GRA (i.e., answered that symptoms were moderately or markedly improved) was 60 of 110 (54.5%) in the PPTNS group and 23 of 110 (20.9%) in the sham group; this difference was statistically significant, $p<0.001$. Intention-to-treat analysis was used for the primary endpoint only. Several secondary outcomes also favored the PPTNS group. The mean reduction in a symptom severity score (a lower score indicates less severity) was 36.7 in the PPTNS group and 29.2 in the sham group, $p=0.01$.

Similarly, the mean reduction in a quality-of-life scale, the SF-36 (a higher score indicates higher quality of life), was 34.2 in the PPTNS group and 20.6 in the sham group, p=0.006. A limitation to this study was that the primary outcome, the GRA, was a single-item subjective measure. In addition, the SUmiT trial only reported comparative data immediately following the initial course of treatment; the study did not evaluate the long-term effectiveness of PPTNS. Unlike medication, which can be taken on an ongoing basis, PPTNS involves an initial 12-week course of treatment, followed by maintenance therapy, which, to date, has not been well-defined. Therefore, the assumption cannot be made that short-term treatment effects will be maintained.

In 2010, MacDiarmid and colleagues reported one-year follow-up data for patients from the OrBIT trial who had been assigned to the PPTNS group and had responded to the initial course of treatment, defined as reporting symptom improvement at 12 weeks. Thirty-three of the 35 responders were included. They received a mean of 12.1 (SD=4.9) treatments between the 12-week and 12-month visits, with a median of 17 days between treatments. Data was available for 32 of the 33 (97%) participants at six months and 25 of the 33 (76%) participants at 12 months. The mean reduction in number of voids per day from baseline (the original primary outcome of the study) was 3.2 (SD=3.7) at six months and 2.8 (SD=3.7) at 12 months. Other voiding diary outcomes at 12 months, based on 25 responses, were mean changes in nocturia episodes of -0.8, in episodes of moderate to severe urgency per day of -3.7, and in episodes of urge incontinence per day of -1.6. As noted above, this analysis was limited in that no data from the tolterodine group was available to compare long-term outcomes. Another limitation was that only PPTNS responders were included, rather than all of the patients assigned to PPTNS treatment.

The evidence for using PPTNS in individuals with fecal incontinence includes several RCTs and systematic reviews. The available RCTs have not found a clear benefit of PPTNS. Neither of the sham-controlled trials found that active stimulation was superior to sham for achieving the primary outcome, at least a 50% reduction in mean weekly fecal incontinence episodes. The evidence is insufficient to determine that this technology results in an improvement in the net health outcome. There are currently no PPTNS devices cleared by the FDA for the treatment of fecal incontinence.

Zyczynski et al (2022) conducted the Neuromodulation for Accidental Bowel Leakage (NOTABLe) sham-controlled trial of percutaneous posterior tibial nerve stimulation (PTNS) in women with fecal incontinence (N=166). Women with greater than or equal to three months of moderate-to-severe fecal incontinence were randomized to PTNS (n=111) or sham stimulation (n=55). Stimulation was delivered in 12 weekly 30-minute sessions to a single lower extremity. The primary outcome was change from baseline in St. Mark score (a 7-item, validated patient-reported outcome) measured after 12 weekly treatments. Secondary outcomes included stool consistency, bowel movement, and stool leakage episodes per week. There was no significant difference between the PTNS group (-5.3 points) and the sham group (-3.9 points) in terms of improvement from baseline in St. Mark scores (adjusted difference -1.3;95% CI, -2.8 to 0.2). There also was no significant difference in reduction in weekly fecal incontinence episodes from baseline between the PTNS group (-2.1 episodes) and sham group (-1.9 episodes) (adjusted difference -0.26; 95% CI, -1.85 to 1.33).

Implantable Peripheral Neurostimulators for the Treatment of Voiding Dysfunction:

Approval for the eCoin Peripheral Neurostimulator was granted based on a prospective, open-label,

multi-site, single arm clinical trial (NCT03556891) of 132 individuals. The primary outcome of the interventional study was the percentage of individuals experiencing 50% or better improvement in urgency urinary incontinence episodes after subcutaneous stimulation of the tibial nerve using the eCoin device, as measured by a 3-day voiding diary capturing the number of Urgency Incontinence Episodes/day, voids per/day, urgency episodes/day, nocturia episodes/day as well as quality of life (via Overactive Bladder Questionnaire). All individuals were successfully implanted with the device. Data was collected at baseline and the primary outcome assessment occurred 48 weeks after device activation. Device activation occurred 4 weeks after implantation. The analysis demonstrated 68% of the individuals were considered responders, experiencing a 50% or better improvement in their symptoms. Measured at 52 weeks post-implantation, 17/133 (12.78%) had experienced an adverse event, which mostly consisted of skin infection (3.01%) and issues with the device itself (14.7%) such as stimulation issues, device dislocation, or device malfunction. The study was funded by the vendor, was unblinded, without a comparator group and limited length of follow-up. Studies with longer-term follow-up and sound methodology are needed.

PROFESSIONAL GUIDELINE(S)

The American Gastroenterological Association (2017) issued an expert review and clinical practice update on surgical interventions and device-aided therapy for the treatment of fecal incontinence. The update stated that "until further evidence is available, percutaneous tibial nerve stimulation should not be used for managing FI in clinical practice."

The American Urological Association and the Society of Urodynamics, Female Pelvic Medicine & Urogenital Reconstruction (2020) published updated guidelines on the diagnosis and treatment of non-neurogenic overactive bladder in adults. The guidelines included a statement that clinicians may offer PTNS as a third-line treatment option in carefully selected patients. The statement carried a grade C rating, indicating that the balance of benefits and risks/burdens are uncertain.

According to the American Urological Association (AUA) and the Society of Urodynamics, Female Pelvic Medicine and Urogenital Reconstruction (SUFU) 2021 guidelines on adult neurogenic lower urinary tract dysfunction (NLUTD), clinicians may offer posterior tibial nerve stimulation to select spontaneous voiding NLUTD individual with urgency, frequency, and/or urgency incontinence. (Conditional Recommendation; Evidence Level: Grade C). PTNS is approved for patients with non-neurogenic OAB, however, it has been shown to offer benefit to select individuals with NLUTD where bladder problems are mainly isolated to storage symptoms. This benefit has primarily been demonstrated in individuals with neurologic diagnoses such as Multiple Sclerosis, Parkinson Disease, and Stroke who have OAB symptoms and continue to volitionally void.

REGULATORY STATUS

In July 2005, the Urgent PC Neuromodulation System (Uroplasty, Inc.) received Section 510(k) marketing clearance from the U.S. Food Drug Administration (FDA) for PPTNS to treat patients suffering from urinary urgency, urinary frequency, and urge incontinence. In 2010, the cleared indication was changed to overactive bladder (OAB) and associated symptoms of urinary urgency, urinary frequency, and urge incontinence. The Urgent PC Neuromodulation System is not FDA-

cleared for other indications, such as the treatment of fecal incontinence.

eCoin received FDA approval on March 1, 2022. This device is indicated for the treatment of urgency urinary incontinence in individuals who are intolerant to or having an inadequate response to other more conservative treatments who have undergone a successful trial of PPTNS.

Current Effective Date	**January 1, 2027**
Next Review Date	**February 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

This policy does not address Transarterial Chemoembolization (TACE). Also, this policy does not address arterially directed therapies other than TARE.

POLICY STATEMENT(S)

I. Transarterial Radioembolization (TARE) using radioactive Yttrium-90 (^{90}Y) microspheres is considered **medically necessary** as a treatment for **EITHER** of the following indications (Refer to Policy Guidelines):

Primary Hepatic Tumors

A. Treatment of unresectable or medically inoperable hepatic tumors including **ANY** of the following:

1. Hepatocellular carcinoma (HCC);
2. As a bridge to transplant for patients with HCC who:
    a. Meet liver transplant criteria and are waiting liver transplantation; **or**
3. Intrahepatic cholangiocarcinoma (ICC);

OR

Metastatic Hepatic Tumors

B. Treatment of unresectable or medically inoperable hepatic metastases when **ALL** of the following criteria are met:

1. Individual is not a candidate for chemotherapy or other systemic therapies, or is refractory to chemotherapy; with **ANY** of the following indications:
    a. Neuroendocrine tumors (e.g., carcinoids, pancreatic islet cell tumors, endocrine tumors)
    b. Colorectal carcinoma;
    c. Breast carcinoma; **or**
    d. Melanoma (ocular or cutaneous).

II. A second (repeat) TARE is considered **medically necessary** when **ALL** of the following criteria

are met (Refer to Policy Guidelines):

A. Treatment is for a new, progressive primary or metastatic hepatic tumor;

B. A previous satisfactory response to an initial radioembolization treatment was attained as evidenced by **all** of the following criteria:

1. Completion of a computed tomography (CT) scan or positron emission tomography (PET)-CT scan, performed 3 months following the previous procedure; **and**
2. Response should be graded according to the revised Response Evaluation Criteria in Solid Tumors (RECIST) guideline (Version 1.1);

C. There are no other effective systemic or liver-directed treatment options available;

D. The individual has compensated liver function tests;

E. Estimated lung dose and combined lung dose from previous radiation are within acceptable dose volume constraints; **and**

F. Treatment should be given to a targeted tumor volume.

III. A third TARE is considered **not medically necessary**.

IV. TARE as a treatment for all other metastatic or primary hepatic tumors is considered **investigational**.

POLICY GUIDELINE(S)

I. TARE should be reserved for patients with:

A. An Eastern Cooperative Oncology Group (ECOG) performance status no greater than 2 or Karnofsky Performance Status (KPS) of 70 or above;

B. Adequate liver function and reserve, and liver-dominant metastases;

C. Life expectancy of greater than three (3) months.

II. Radioactive Yttrium-90 (90Y) microspheres treatment is allowed only in the outpatient setting unless the documentation supports the medical necessity of inpatient treatment.

DESCRIPTION

Hepatic tumors can arise either as primary liver cancer or by metastasis to the liver from other tissues or organs. At present, surgical resection with tumor-free margins and liver transplantation are the only potentially curative treatments for hepatic cancer. Unfortunately, most hepatic tumors are not amenable to resection or transplantation at diagnosis, due to their anatomic location, tumor size, the number of lesions, concurrent nonmalignant liver disease, or insufficient hepatic reserve. Patients with hepatic tumors may require treatments to downstage disease to meet criteria for a liver transplant (Milan criteria, etc.) and those individuals who do meet become candidates often require bridge therapy due to the long waiting time to obtain the transplant. Various minimally invasive ablative techniques have been investigated that seek to cure or palliate unresectable hepatic tumors by improving loco-regional control. Examples of these techniques include TARE, transarterial chemoembolization, and thermal ablative techniques such as radiofrequency ablation, cryotherapy, and microwave ablation.

The content of this policy addresses the use of TARE, is also known in the literature as Selective Internal Radiation Therapy (SIRT), and arterial radioembolization with yttrium-90 (^{90}Y). TARE relies on targeted delivery of small beads (microspheres) impregnated with ^{90}Y, a radioactive beta emitter with a short half-life of 64.2 hours (2.67 days). TARE uses local anesthesia and fluoroscopic guidance to inject the radioactive material into the left, right or common hepatic artery via a percutaneous (femoral or gastroduodenal) catheter. This allows the delivery of a concentrated dosage of radiation directly into the tumor bed, while conserving the normal liver tissue that surrounds the tumor. The size of the microspheres causes them to become entrapped within the tumor vasculature and retained. The treatment goals with TARE can include curative intent, bridging to transplant, downsizing disease to assist with resection, inform the treatment approach and to provide valuable information for radiation dosimetry. TARE can usually be performed in an outpatient setting, as there is no radiation exposure to others once the microspheres have been infused.

Eastern Cooperative Oncology Group (ECOG) Performance Status (Oken et al 1982)

Performance Status	Description
0	Fully active; no performance restrictions
1	Strenuous physical activity restricted; fully ambulatory and able to carry out light work
2	Capable of all self-care but unable to carry out any work activities Up and about > 50% of waking hours.
3	Capable of only limited self-care; confined to bed or chair > 50% of waking hours
4	Completely disabled; cannot carry out any self-care; totally confined to bed or chair

SUPPORTIVE LITERATURE

Hepatocellular Carcinoma (HCC)

TARE has been studied for its use in all stages of HCC and has demonstrated comparable outcomes to the historical therapies of choice, including transarterial chemoembolization for intermediate stage HCC, and systemic therapy in patients with advanced HCC.

In 2016, Salem and colleagues conducted a randomized phase II trial (PREMIERE) comparing TARE to TACE in 179 patients with HCC with a Barcelona Clinic Liver Cancer stage of A or B. There was no difference noted in overall survival (OS), but authors found that TARE provided significantly longer time to progression (TTP) over TACE, patients had fewer related adverse events, and improved quality of life. Authors concluded that given these outcomes, TARE provides better tumor control, and further, that it could reduce the number of patients who drop out of the liver transplant waitlists.

The LEGACY Study (Salem 2021) evaluated TARE as a primary treatment of naïve solitary HCC tumors less than or equal to 8 cm in size. The retrospective single arm study evaluated the overall response (OR) rate and duration of response and determined an OR of 88.3% with 62.2% of the lesions having a duration of response greater than six months, which again, is critical for patients awaiting transplant. The patients that had received surgical resection or transplant had an overall survival of 86.6% and 92.8%. Authors concluded that radioembolization for solitary HCC is safe and efficacious when neoadjuvant to transplant or resection, or as a stand-alone treatment.

Trials have demonstrated that there is no difference in OS or progression free survival (PFS) when comparing TARE with the use of the use of tyrosine kinase inhibitor sorafenib (Vilgrain 2017) for the treatment of HCC. Additionally, better treatment tolerance, and less adverse effects were noted with TARE.

Neuroendocrine Tumors

While studies investigating TARE for neuroendocrine tumors have limitations such as heterogeneous patient populations, studies report relief of symptoms from carcinoid syndrome in a proportion of patients. Surgical debulking of liver metastases has shown palliation of hormonal symptoms; debulking by radioembolization may lead to symptom relief in some patients (e.g., Sato et al 2008; Kennedy et al 2009; Cao et al 2010; Cramer et al 2016).

Metastatic Colorectal Cancer

A major cause of morbidity and mortality in patients with colorectal disease when metastatic to the liver is liver failure, as this disease tends to progress to diffuse, liver-dominant involvement. The literature demonstrates that the use of TARE to decrease tumor bulk or halt TTP and liver failure, may lead to prolonged PFS and OS in patients with no other treatment options (e.g., those with chemotherapy refractory liver-dominant disease). Other uses include palliation of symptoms (e.g., Kennedy et al 2009, 2016; Mulcahy et al 2009; Hendlisz et al 2010; Damm et al 2016; Jakobs et al 2017).

In a 2021 randomized phase III trial, Mulcahy et al investigated the role of TARE when combined with standard-of care second-line systemic chemotherapy for the treatment of colorectal liver

metastases. The study was conducted in over 95 centers internationally and included 488 patients whose disease had progressed despite first-line chemotherapy. The patients were randomly assigned to chemotherapy with or without TARE. Primary end points were PFS and hepatic PFS (hPFS) from the time of group assignment using RECIST 1.1. Results demonstrated that the primary end points of PFS and hPFS were longer with the addition of TARE to second-line chemotherapy. Further, TTP was observed for tumors with KRAS mutation, left-side primary tumor, hepatic tumor burden of 10%-25%, ≤ 3 lesions, addition of a biologic agent, and resected primary disease. The study was limited by its design, in that it was not powered for OS, and higher rates of additional local therapy (including TARE) occurred in the control arm; which prevents the ability to draw strong conclusions based on the results. Authors determined that although the addition of TARE to systemic therapy improved PFS and hPFS in second-line settings for colorectal liver metastases, further studies are needed to identify the optimal second-line patient population that would most benefit from treatment.

Bridge Therapy

Gabr et al (2020) performed a retrospective review reporting the long-term outcomes of 207 liver transplantation patients with HCC who were bridged or down staged with TARE from 2004 to 2018. The median OS from liver transplant was 12.5 years, with a median time to liver transplantation of 7.5 months (interquartile range, 4.4 to 10.3). Overall, 169 patients were bridged and 38 were down staged. The OS rates at 3, 5, and 10 years were 84%, 77%, and 60%, respectively. Disease specific mortality was 6%, 11%, and 16% at 3, 5, and 10 years. No differences were noted in recurrence free survival and OS for patients who were bridged or down staged. Recurrence free survival was greater in patients with complete/extensive tumor necrosis vs. partial. Authors came to the concluded TARE is an effective treatment for HCC in the setting of bridging/downstaging to liver transplant.

Lopez et al conducted a systematic literature review (2023) to analyze relevant data regarding patient selection, HCC features and outcomes after TARE for downstaging or bridging in liver transplant. A total of 14 studies representative of 204 patients were included in the analysis, which was made up of the following treatments included in the studies: downstaging (n=7), bridging (n=3), and mixed (downstaging and bridging, n=4). For patients with remaining viable tumor after imaging, or for those who had planned staged procedures due to bilobar disease, multiple TARE interventions were required (16.7% to 28% of patients). A total of 55 patients were transplanted after undergoing TARE for downstaging. The percentage of patients who received a response, by study group and type is as follows:

Study Group	Complete Response	Partial Response	Stable Disease	Progressive Disease
Downstaging	26.7%	49.2%	13.4%	10.7%
Bridging	41.8%	34.1%	17.6%	6.6%
Mixed	30.8%	35.9%	33.3%	0%

Despite limitations including study design, high dropout rates due to death or tumor progression, and authors believing comparisons to be underpowered, they concluded that the use of TARE is an alternative treatment in patients with advanced HCC who were not initially suitable for resection or

liver transplant.

Other Hepatic Metastases

A 2024 study (NCT 02685631) by Zhou et al aimed to evaluate the response and survival outcomes of TARE on unresectable liver-dominant metastases from primary neoplasms other than colorectal carcinoma (m-non-CRC). The study included 1474 patients from the Radiation-Emitting Society of Interventional Radiology SIR-Spheres in Nonresectable Liver Tumor registry (RESiN). Of the study participants, 33% had liver metastases of non-colorectal origin, 34% had metastatic colorectal cancer, 34% had HCC). Responses were identified in 12 unique cancer types, most of which were identified as refractory to several lines of systemic therapies. Outcomes provided within the study were as follows:

Study Group	**Complete Response**	**Partial Response**	**Stable Disease**	**Progressive Disease**	**Objective Response Rate**	**Disease Control Rate**	**Median Duration of Response**
m-CRC n=248	Not Available	Not Available	Not Available	31%	31%	69%	9 months (95% CI, 6–13 months)
m-non-CRC n=250	6%	39%	28%	27%	46%	73%	11.5 months (95% CI, 8–19 months) for m-non-CRC (P = .04 for comparison between mCRC and m-non-CRC groups).
HCC n=255	Not Available	Not Available	Not Available	21%	50%	79%	16 months (95% CI, 11–19 months) for HCC

The study demonstrated better outcomes with the m-non-CRC group for duration of response, PFS, TTP, and OS when compared to the reference standard for metastatic colorectal cancer. Metastatic

neuroendocrine tumor, sarcoma, ovarian, renal, prostate, and breast cancers were associated with superior treatment outcomes. Worse treatment outcomes were observed in metastatic lung, gastric, pancreatic, and esophageal cancers. Although promising for certain indications, this study did have several limitations including its design which did not include a control arm or predefined number of patients for each cancer type. The patient population was heterogeneous and obtained from RESiN, a non- randomized observational registry and therefore, differences in patient's extent of disease, treatment timing and use of other therapies does not allow for applicability to the general population. Authors concluded that despite its limitations, the use of TARE in m-non-CRC patients may provide an important option for some patients with late-stage disease whose malignancies are rarer.

Melanomas

A 2017 systematic review by Jia et al aimed to assess the effectiveness of TARE in the treatment of unresectable liver metastases from melanoma. A total of 12 reports were included in the analysis, of which, 7 were observational studies and 5 were conference abstracts. The reports represented 255 patients with primary sites of melanoma consisting of cutaneous (8.6%), ocular (77.3%), rectal (1.2%) and unknown (12.9%). Among the 207 patients, complete response was seen in 1.0% (2/207), partial response was seen in 19.3% (40/207), stable disease was seen in 46.9% (97/207), and progressive disease was seen in 32.9% (68/207). The median survival was 10 months (range, 7-13.4 months), and the median 1-year survival rate was 34.6% (range, 23%-80%). Authors concluded that TARE is a promising alternative therapy with encouraging effects on disease control and survival in patients with melanoma, given the lack of alternative treatments for this patient population.

A prospective phase II trial (NCT01473004) from Gonsalves and colleagues (2019) aimed to assess the safety and effectiveness of TARE for the treatment of uveal melanoma hepatic metastases by studying the level of response, PFS, and OS after TARE, comparing treatment naïve participants (Group A, n=23) to patients who progressed after immmunoembolization, who had less than a 50% tumor burden (Group B, n=24). Patients were followed for 1 month and then every 3 months for toxicities, with MRI, CT and PET performed every 3 months. Patients were followed for a minimum of 2 years or until death. A median OS of 18.5 months and 19.2 months with a 1-year survival of 60.9% and 69.6% was achieved in treatment Groups A and B, respectively. Survival outcomes were attributed to the stabilization of hepatic tumors in 87.0% and 58.3% of participants in groups A and B, respectively. Additionally, PFS was 8.1 months and 5.2 months for group A and B participants, respectively. Despite the stabilization noted, greater than 90% of participants developed new hepatic and extrahepatic metastases following treatment. The treatment was well tolerated with no instances of radiation-induced liver disease and clinically significant treatment-related toxicities were temporary and uncommon. The authors concluded that given there are no effective systemic treatments available for metastatic uveal melanoma, radioembolization is a safe and effective first-or second-line treatment for uveal melanoma hepatic metastases.

A retrospective analysis (Ponti et al 2020) of a prospectively collected cohort was conducted evaluating 22 patients with uveal melanoma metastatic to the liver and treated with first-line TARE. Authors set to investigate the safety and efficacy of TARE as a first-line therapy, given data were lacking when compared to its use as salvage therapy. According to the European Association of the

Study of Liver Disease (EASL) Criteria, disease control at 6 months after TARE was achieved in 15 of the 29 TARE patients and was predictive of survival. Median overall survival from the first TARE was 18 months (95% confidence interval [CI], 8–28 months). At the time of the analysis, 5 patients (23%) had survived. In multivariate analysis, largest lesion size (hazard ratio [HR], 1.22; 95%CI, 0.98–1.53], liver tumor volume (HR, 1.002; 95%CI, 1.0004–1.003), subsequent systemic therapy (HR, 0.04; 95%CI, 0.006–0.24), and liver-directed locoregional therapy (HR, 0.204; 95%CI, 0.04–0.94) were predictive of survival. The authors concluded that based on study results, TARE is safe and produced promising outcomes in patients with uveal melanoma metastatic to the liver, but that prospective trials using first-line TARE are desirable.

Intrahepatic Cholangiocarcinoma (ICC)

To investigate the efficacy and survival profile of TARE for unresectable ICC, Schartz et al 2022 conducted a systematic review and meta-analysis of 21 studies representing 921 patients using a random effects model. The study measured for disease control rate (DCR), down staged-to resectable rate, cancer antigen CA 19-9 response rate, pooled median OS, pooled median PFS, and mean reported survival rates from 3 to 36 months. The overall DCR was 82.3%. In 11% of the cases, patients were down staged to being surgically resectable. The CA 19-9 response rate was 67.2%. From the time of radioembolization, PFS was 7.8 months and median OS was 12.7 months. The mean overall reported survival proportions were 84% at 3 months, 69% at 6 months, 47% at 12 months, 31% at 18 months, 30% at 24 months, 21% at 30 months, and 5% at 36 months. The authors conclude that TARE for unresectable ICC results in substantial downstaging, disease control, and survival.

In an effort to identify factors associated with an improved median OS in ICC patients receiving radioembolization, Schaarschmidt and colleagues (2023) conducted a retrospective study of five major tertiary care centers. The study analyzed outcomes of 138 radioembolizations conducted in 128 patients with ICC. Radioembolization was performed as first-line treatment in 25.4%, as second-line treatment in 38.4%, and as salvage treatment in 36.2%. The disease control rate was 68.6%, 52.8%, and 54.0% respectively, after 3 months; 31.4%, 15.1%, and 12.0% after 6 months; and 17.1%, 5.7%, and 6.0% after one year. In patients receiving radioembolization as first-line, second-line, and salvage treatment, Median OS was 12.0 months for patients receiving radioembolization as first-line treatment, 11.8 months for patients receiving second-line treatment, and 8.4 months for those with salvage treatment. No significant differences were observed between the three groups (P=0.15). Limitations of the study were noted, including its retrospective design, with selection bias potential due to a high probability that radioembolization was reserved for patients who were ineligible for surgery or chemotherapy, and the likelihood that patients with comorbidities were included in the cohort for a first-line radioembolization. Given the limitations, authors conclude that second-line and salvage radioembolization may be an important option for advanced ICC, and that its use as a first-line therapy requires further investigation.

Breast

Liu et al (2022) published a systematic review and meta-analysis assessing the evidence for TARE in liver metastatic breast cancer. A total of 24 studies (N=412) were included, most of which were retrospective or non-comparative. Patient demographic information was not summarized. The median

survival time after TARE was 9.8 months. The cumulative OS rates at 6 months and one, two, and three years were 65.6% (95% CI, 60.8% to 70.0%), 39.0% (95% CI, 34.3% to 43.7%), 13.3% (95% CI, 10.3% to 16.8%), and 4.4% (95% CI, 2.7% to 6.6%), respectively. Patients who had a hepatic metastatic burden exceeding 25% experienced a median survival time of 6.8 months, while those with a burden less than 25% had a median survival time of 10.5 months (p<.0001).

PROFESSIONAL GUIDELINE(S)

The National Comprehensive Cancer Network (NCCN) V.2.2025 Guidelines for Hepatocellular Carcinoma recommend TARE as bridge therapy to decrease tumor progression and the dropout rate from the liver transplantation waiting list.

The NCCN V.2.2025 Guidelines for Biliary Tract Cancers (Intrahepatic Cholangiocarcinoma) recommends arterially directed therapies alone or followed by systemic chemotherapy with the intention to prolong survival or downstage ICC to curative resection.

The NCCN Guidelines for Uveal Melanoma V.6.2025 recommends TARE. Recommendations are based upon disease control rates being consistently greater than 50% in retrospective studies. Additionally, the treatment is well tolerated, with most toxicities being grade 1-2 and self-limiting, with no treatment related deaths.

The American Association for the Study of Liver Diseases (AASLD), in an updated 2023 practice guideline regarding the prevention, diagnosis, and treatment of individuals with HCC, states that the use of TARE with Yttrium-90 has been established as an acceptable treatment for solitary unresectable HCC, and there are increasing data for its utilization to enhance the future liver remnant size. Enhancing the future liver remnant size before resection ensures the remaining liver can adequately function after diseased tissue removal. Additionally, regarding use of TARE as a bridge to transplant, the AASLD highlights that due to the mandatory 6-month wait time prior to the awarding of Model for End-Stage Liver Disease (MELD) exception, neoadjuvant treatment is typically used as a bridge to control tumor growth and reduce the risk of waitlist dropout (Singal et al 2023).

A joint practice parameter on the use of TARE for the treatment of liver malignancies was published by the American College of Radiology (ACR), American Brachytherapy Society (ABS), American College of Nuclear Medicine (ACNM), American Society for Radiation Oncology (ASTRO), Society of Interventional Radiology (SIR), and Society of Nuclear Medicine and Molecular Imaging (SNMMI) (Hong et al 2021). The practice parameter defines indications for TARE which include the following:

- The presence of unresectable or inoperable primary or secondary liver malignancies (particularly colorectal cancer and neuroendocrine tumor metastases).
- The tumor burden should be liver dominant, not necessarily exclusive to the liver.
- Patients should also have a performance status that will allow them to benefit from such therapy.
- Life expectancy of at least 3 months.

The American College of Radiology (ACR) (Koepsel et al 2022) published ACR Appropriateness Criteria for the Management of Liver Cancer stating that TARE is appropriate for the treatment of the

following indications:

HCC

- Solitary tumor less than 3 cm, cirrhotic
- Solitary tumor 3 to 5 cm, cirrhotic
- Multifocal, bilobar disease, at least 1 tumor greater than 5 cm, cirrhotic
- Solitary or multifocal disease with vascular invasion, cirrhotic

Intrahepatic Cholangiocarcinoma

- Peripheral hepatic lobar cholangiocarcinoma, less than 3 cm; no biliary ductal dilatation, macroscopic vascular invasion, regional lymphadenopathy, or distant metastases

Ductal Cholangiocarcinoma

- Hilar cholangiocarcinoma, greater than 3 cm with poorly defined margins, vascular invasion, and periportal lymphadenopathy

Metastatic Liver Disease

- Multifocal metastatic neuroendocrine tumor (includes carcinoid tumors as well as islet cell tumors of the pancreas)
- Multifocal bilobar colorectal carcinoma (liver dominant or isolated)

REGULATORY STATUS

There are currently two types of Yttrium microspheres (glass and resin) that have been approved by the FDA and are classified as brachytherapy devices: TheraSpheres (Theragenics; Atlanta, GA) and SIR-Spheres (Sirtex Medical Limited; Lake Forest, IL). The FDA granted premarket approval of SIR-Spheres in 2002 for use in combination with 5-floxuridine (5-FUDR) chemotherapy to treat unresectable hepatic metastases from colorectal cancer. In contrast, the FDA approved TheraSpheres under the humanitarian device exemption (HDE) in 1999 for use as monotherapy to treat unresectable HCC. In January 2007, the HDE for TheraSpheres was expanded to include patients with HCC who have partial or branch portal vein thrombosis. In March of 2021, the FDA granted approval of the TheraSphere Y-90 Glass Microspheres, developed for the treatment of patients with HCC expanding access to this which previously could only have been used under an HDE.

The U.S. Food and Drug Administration (FDA) regulates these as medical devices. All devices including related components require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2026 Jan 15]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most serious type of recalls. Available from: Medical Device Recalls | FDA [accessed 2026 Jan 15]

CODE(S)

- Codes may not be covered under all circumstances.
- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
37243	Vascular embolization or occlusion, inclusive of all radiological supervision and interpretation, intraprocedural roadmapping, and imaging guidance necessary to complete the intervention; for tumors, organ ischemia, or infraction
75894	Transcatheter therapy, embolization, any method, radiological supervision and interpretation
77778	Interstitial radiation source application, complex, includes supervision, handling, loading of radiation source, when performed
79445	Radiopharmaceutical therapy, by intra-arterial particulate administration

MEDICAL POLICY

Medical Policy Title	Transcranial Magnetic Stimulation and Cranial Electrotherapy Stimulation
Policy Number	3.01.09
Current Effective Date	September 1, 2026
Next Review Date	January 2027

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

Major Depressive Disorder (MDD)

I. An initial course of transcranial magnetic stimulation (TMS) is considered **medically appropriate** as a treatment for MDD, severe when **ALL** of the following have been met:

   A. TMS is administered by a U.S. Food and Drug Administration (FDA) cleared device in accordance with the FDA labeled indications;

   B. Member is 15 years or older;

   C. Documented diagnosis of major depressive disorder, severe (single or recurrent), without psychosis, confirmed by standardized rating scales that reliably measure depressive symptoms;

   D. During the current episode of depression, there is a documented failure of **both** of the following:

      1. An adequate trial of an evidence-based psychotherapy known to be effective for major depressive disorder, without clinically significant improvement; **and**

      2. An adequate trial of medication, as documented by **one (1)** of the following:

         a. For adults (age 18 years or older), failure to respond to **both** of the following:

            i. Two (2) or more separate and distinct trials of antidepressant medication from two different classes, each at minimum therapeutic dose for at least 8-weeks, unless there is a documented serious side effect; **and**

            ii. One (1) augmentation with a different class of antidepressant or another agent known to improve depression outcomes, at or above the minimal therapeutic dose for at least 8-weeks, unless there is a documented serious side effect; **or**

         b. For adolescents (age 15 to 17 years), failure to respond to two (2) or more trials of FDA-approved anti-depressant medications at or above the minimal therapeutic dose for at least 8-weeks, unless there is a documented serious side effect;

E. Absence of an absolute contraindication to TMS, and relative contraindications (if applicable) were assessed and deemed safe for administering TMS (see Policy Guideline I.).

II. TMS retreatment is considered **medically appropriate** for the treatment of MDD, severe when **ALL** of the following criteria are met:

A. TMS is administered by an FDA-cleared device in accordance with the FDA labeled indications;

B. All criteria for an initial course of TMS treatment were met (See Policy Statement I.);

C. A new episode of major depression, severe is documented by standardized rating scales;

D. The member responded to prior treatments, as evidenced by a greater than 50% improvement in standard rating scale measurements for depressive symptoms;

E. It has been at least three (3) months since the end of the initial TMS treatment course.

Obsessive-Compulsive Disorder (OCD)

III. An initial course of transcranial magnetic stimulation (TMS) is considered **medically appropriate** as a treatment for OCD when **ALL** of the following have been met:

A. TMS is administered by an FDA-cleared device, in accordance with the FDA labeled indications;

B. Member is 18 years or older;

C. Documented diagnosis of OCD as defined by the most recent edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM);

D. Resistance to treatment evidenced by persistent OCD symptoms is documented by a Yale-Brown Obsessive-Compulsive Scale (Y-BOCS) score after **both** of the following:

1. An adequate trial of evidenced-based psychotherapy known to be effective for OCD, without clinically significant improvement (e.g., exposure response prevention [ERP], cognitive behavioral therapy [CBT], acceptance and commitment therapy [ACT]); **and**

2. Two (2) or more separate and distinct trials of psychopharmacologic medications known to treat OCD, each at the minimum therapeutic dose for at least 8 weeks, unless there is a documented serious side effect;

E. Absence of any absolute contraindication to TMS, and relative contraindications (if applicable) were assessed and deemed safe for administering TMS (see Policy Guideline I.).

IV. TMS retreatment is considered **medically appropriate** for the treatment of OCD when **ALL** of the following criteria are met:

A. TMS is administered by an FDA-cleared device, in accordance with the FDA labeled indications;

B. All criteria for initial course of TMS treatment were met (see Policy Statement III.);

C. The member responded to prior treatments, as evidenced by **both** of the following:
   1. At least a 30% reduction in the Yale-Brown Obsessive-Compulsive Scale (Y-BOCS) score; **and**
   2. It has been at least three (3) months since the end of the initial TMS treatment course.

Not Medically Necessary

V. TMS is considered **not medically necessary** for **EITHER** of the following:
   A. As a treatment for major depressive disorder or obsessive-compulsive disorder that does not meet all the above criteria;
   B. Reassessment of motor threshold following the first TMS treatment session, unless medical records document a clinical concern indicating a potential change in stimulation requirements (e.g., medication adjustments).

Investigational

VI. TMS is considered **investigational** for **ANY** of the following:
   A. TMS sessions beyond the standard course of 36 sessions, as continuation of the initial course or as maintenance/preservation therapy;
   B. TMS as a treatment for all other psychiatric and/or neurological disorders, including but not limited to: bipolar disorder, borderline personality disorder, schizophrenia, substance use or addictive disorders substance use or addictive disorders (e.g., alcohol, caffeine, cannabis, tobacco, gambling), migraine headaches (via single-pulse), stroke);
   C. Use of any TMS device or stimulation protocol not FDA-cleared, including but not limited to: bilateral stimulation, EEG-synchronized TMS, low-frequency protocols, Magnetic e-Resonance Therapy (MeRT), precuneus-targeted magnetic stimulation, priming techniques, and quadripulse stimulation);
   D. Magnetic resonance imaging (MRI)-guided TMS, including but not limited to functional connectivity MRI (fc-MRI)-guided stimulation;
   E. Accelerated treatment protocols, delivering more than one (1) TMS session per day, including the Stanford Accelerated Intelligent Neuromodulation Therapy (SAINT) protocol;
   F. Adjunct use of ketamine with TMS;

VII. Cranial electrotherapy stimulation (CES) (also known as transcranial electrical stimulation [tES] or cranial electrical stimulation) is considered **investigational** for **ALL** indications, including but not limited to anxiety, depression, and insomnia.

POLICY GUIDELINE(S)

I. Contraindications of TMS include the following:

   A. Absolute:

      1. Presence of ferromagnetic or magnetic sensitive metal in the head or neck areas in close proximity to the TMS coil magnetic fields (e.g., metal/bullet fragments, cochlear implants, brain stimulators or electrodes, aneurysm clips or coils, vagus nerve stimulator);

      2. Presence of acute or chronic psychotic symptoms or disorders (e.g., schizophrenia, schizophreniform or schizoaffective disorder) in the current depressive episode.

   B. Relative:

      1. Implanted cardiac pacemaker or implantable cardiac defibrillator (ICD);

      2. History of seizures with increased risk of seizure);

      3. Neurologic conditions (e.g., epilepsy, cerebrovascular disease, dementia, increased intracranial pressure, history of repetitive head trauma or with primary or secondary tumors in the central nervous system;

      4. Presence of a brain lesion (vascular, traumatic, neoplastic, infectious, or metabolic.

II. TMS must be performed by physicians who are adequately trained and experienced in the specific techniques used. The order for treatment (or re-treatment) should be written by a physician (MD or DO) who has examined the patient and reviewed the record. The treatment must be given under the direct supervision of the ordering physician, i.e., the physician must be in the area and be immediately available.

III. Accelerated TMS delivers multiple TMS sessions per day, completing the full therapeutic dose in days rather than weeks. This approach aims to achieve faster symptom relief for MDD while reducing the treatment burden/barrier of near-daily clinic visits over several weeks.

   A. Accelerated deep intermittent theta burst (iTBS), using the BrainsWay Deep System, is an FDA-cleared treatment protocol for MDD that does not require image-guided targeting or automated session delivery.

   B. Accelerated iTBS, using the Magnus Medical SAINT Neuromodulation System (known as the SAINT protocol), is an FDA-cleared treatment protocol requiring resting-state functional connectivity MRI (fcMRI) and neuronavigation.

IV. When requesting TMS, providers are required to submit documentation of prior medication trials, including the approximate duration (start and end dates), dosing, and side effects. An adequate trial of medication is based on a combination of appropriate duration (typically 4 to 6 weeks),

therapeutic dosage, tolerance, and clinical response.

V. Standardized rating scales considered reliable in rating depressive symptoms include validated depression monitoring scales such as: Geriatric Depression Scale (GDS); Personal Health Questionnaire Depression Scale (PHQ-9); Beck Depression Scale (BDI); Hamilton Rating Scale for Depression (HAM-D); Montgomery Asberg Depression Rating Scale (MADRS); Quick Inventory of Depressive Symptomatology (QIDS); and Inventory for Depressive Symptomatology Systems Review (IDS-SR).

DESCRIPTION

Transcranial Magnetic Stimulation (TMS)

TMS is a noninvasive neuromodulation technique that uses a coil placed on the scalp to deliver rapidly alternating electrical currents. These currents generate a magnetic field that passes through the scalp and skull without resistance, inducing localized electrical activity in the underlying cortical neurons. By modulating neural circuits involved in mood regulation and cognitive function, TMS alters brain activity in targeted regions, making it a valuable therapeutic tool in the treatment of neuropsychiatric conditions such as major depressive disorder (MDD).

Stimulation parameters, including cranial location, stimulation frequency, pattern, duration, intensity, and the state of the brain under the coil can be adjusted to influence excitability in specific cortical regions. The standard figure-8 coil primarily stimulates superficial cortical areas and penetrates only 1.5–2 cm beneath the skull, limiting its ability to reach deeper structures. H-coils were developed to address this limitation, which to enable broader and deeper stimulation (up to 4–5 cm) and are available in different models for specific indications, including: the H1 coil targets bilateral dorsolateral prefrontal cortices for MDD, the H7 coil focuses on medial prefrontal and anterior cingulate regions for obsessive-compulsive disorder (OCD), and other coils (e.g., H4) are used for smoking cessation.

Standard repetitive TMS (rTMS) delivers repeated electromagnetic pulses through a coil positioned on the scalp, typically targeting the dorsolateral prefrontal cortex (DLPFC), a region associated with mood regulation. The therapeutic effect depends on stimulation frequency, with high-frequency rTMS (≥10 Hertz [Hz]) being excitatory and enhances neural activity, while low-frequency rTMS (≤1 Hz) is inhibitory and reduces neural excitability. At total of 30 sessions with an optional 6 session taper are delivered over 20–40 minutes once daily over 4–6 weeks. When both high- and low-frequency stimulation are applied to opposite hemispheres during the same session, the protocol is referred to as bilateral rTMS.

Standard Deep TMS (dTMS) uses an H-coil to deliver magnetic pulses to deeper and broader brain regions, reaching 4–5 cm beneath the skull. Depending on indication, dTMS targets cortical and subcortical structures such as the DLPFC and medial prefrontal cortex. At total of 30 sessions with an optional 6 session taper are delivered once daily over 4–6 weeks.

Theta Burst Stimulation (TBS) is a patterned form of rTMS that delivers bursts of high-frequency pulses designed to mimic the brain's natural theta rhythms associated with learning and synaptic

plasticity. The two main subtypes include:

- Standard intermittent TBS (iTBS) is FDA-cleared for MDD and is distinct from accelerated protocols. While not considered accelerated, it is delivered significantly faster than traditional rTMS, targeting the left DLPFC using short bursts of 50 Hz pulses repeated at 5 Hz. A typical session delivers 600 pulses of iTBS over approximately 3 minutes, administered once daily for a total of 36 sessions (30 sessions plus an optional 6 session taper).
- Continuous TBS (cTBS) has inhibitory effects and delivers bursts continuously 40 seconds (600 pulses total). This protocol is not FDA-cleared at this time.

Accelerated TMS (aTMS) refers to multiple TMS sessions per day within a condensed timeframe, aiming to deliver the full therapeutic dose in days rather than weeks. This approach addresses two major limitations of standard TMS: delayed antidepressant effect and treatment burden, which often impairs adherence and access. Two accelerated TMS subtypes have received FDA clearance for MDD:

- Accelerated deep TMS with intermittent theta burst stimulation (ad-iTBS), using the BrainsWay Deep TMS System (H1 coil) without neuronavigation, was FDA-cleared in 2025. The protocol utilizes iTBS stimulation delivered in 5 sessions per day for 6 consecutive days (acute phase), followed by 2 sessions per day weekly for 4 weeks (continuation phase), totaling 38 sessions and approximately 75,000 pulses. Each session delivers approximately 1,980 pulses and lasts under 10 minutes.
- Accelerated iTBS (aiTBS) with resting-state functional connectivity MRI (fcMRI) and neuronavigation, using the Magnus Medical SAINT Neuromodulation System, was FDA-cleared in 2022. The SAINT protocol delivers 1,800 pulses per session at 90% of resting motor threshold, adjusted for cortical depth, with 10 sessions per day spaced 50 minutes apart for 5 consecutive days, totaling 50 sessions, each lasting about 3 minutes.

For TMS targeting, the location of stimulation determines TMS effects. For depression, the left DLPFC is commonly targeted, while the medial prefrontal cortex and anterior cingulate cortex are targeted for OCD. Early methods like the "5 cm rule" (and updated 5.5–6 cm rules) fail to account for anatomical variability. Alternatives include scalp-based strategies (Beam F3), anatomical MRI with neuronavigation, and emerging approaches using resting-state fMRI to personalize targeting based on functional connectivity.

Preservation strategies aim to sustain therapeutic response post-acute treatment and include maintenance, continuation, relapse-prevention, and rescue TMS. These approaches are used in clinical practice but are not FDA-approved as formal protocols.

Bilateral TMS applies high-frequency stimulation to the left DLPFC and low-frequency stimulation to the right DLPFC within the same treatment session, either sequentially or simultaneously. This approach is based on the hypothesis that enhancing excitatory activity on the left and reducing hyperactivity on the right may engage complementary mechanisms to improve clinical outcomes. Investigated for conditions like attention deficit hyperactivity disorder (ADHD), Parkinson's disease, and tinnitus, but remains experimental.

Single-pulse TMS delivers a single magnetic pulse to the cortex to induce a brief neuronal response, for diagnostic and research purposes, assessing cortical excitability and conduction pathways. It does not produce lasting neuromodulatory effects and is not considered a therapeutic intervention.

Cranial Electrotherapy Stimulation (CES)

CES differs from TMS primarily in its delivery method: CES is a non-invasive neuromodulation technique that applies low-level electrical currents through electrodes placed on the earlobes or scalp, whereas TMS uses magnetic fields to stimulate specific brain regions.

CES is conceptually similar to transcranial electrical stimulation (tES), an umbrella term that includes methods such as transcranial direct current stimulation (tDCS) and transcranial alternating current stimulation (tACS), all of which aim to modulate brain activity through externally applied electrical currents. From a regulatory perspective, the FDA classifies CES devices as Class II (special controls) for indications such as anxiety and insomnia, while depression requires Premarket Approval (PMA). The approved Flow FL-100 device (PMA P230024, December 8, 2025) operates using tDCS technology, but the FDA officially lists it under the CES category. This means that while the mechanism is tDCS, the regulatory classification is CES. CES and tDCS are therefore similar in concept but differ in current intensity, electrode placement, and historical regulatory pathways. CES has been evaluated for conditions including anxiety, insomnia, depression, pain, and functional constipation, with FDA clearance for anxiety and insomnia and PMA approval for major depressive disorder.

SUPPORTIVE LITERATURE

Standard TMS for Adults with Major Depressive Disorder (MDD)

The evidence supporting TMS for patients with treatment resistant MDD is robust. Multiple double-blind, randomized, sham-controlled trials demonstrate that stimulation of the left dorsolateral prefrontal cortex (DLPFC) produces a clinically meaningful reduction in depressive symptoms, with a large effect size (e.g., Ontario Health 2007; O'Reardon 2007; Lam 2008; Avery 2008; Janicak 2010; George 2010; Kedzior 2015; Voigt 2021). Overall, the evidence is sufficient to conclude that rTMS leads to a significant improvement in net health outcomes and is considered an appropriate treatment option for patients with MDD who meet established clinical criteria.

Papakostas et al (2024) identified a critical evidence gap regarding the comparative effectiveness of pharmacological and non-pharmacological augmentation strategies versus switching antidepressants in TRD. To address this, they conducted a multi-site, 8-week, randomized, open-label trial comparing augmentation with aripiprazole or rTMS to switching to venlafaxine XR (or duloxetine for those ineligible for venlafaxine). The primary outcome was the change in Montgomery–Asberg Depression Rating Scale (MADRS) scores. A total of 278 participants with treatment resistant depression (TRD) of at least 12 weeks' duration were randomized in a 1:1:1 ratio to one of the three interventions. Of these, 260 participants (rTMS: n=70; aripiprazole: n=92; venlafaxine/duloxetine: n=98) were included in the modified intention-to-treat (MITT) analysis. Post-baseline assessments occurred at weeks 1, 2, 3, 4, 6, and 8, with MADRS evaluations conducted by raters blinded to treatment assignment. Results showed that rTMS augmentation was significantly superior to switching on

MADRS scores (p = 0.015), whereas aripiprazole augmentation did not reach statistical significance (p = 0.069). Conversely, aripiprazole augmentation was significantly superior to switching on self-reported depressive symptoms (p = 0.003), while rTMS showed a trend toward significance (p = 0.031). The authors concluded that rTMS augmentation demonstrated moderate-to-large superiority over switching to venlafaxine XR/duloxetine in clinician-rated depressive symptoms. However, the study's open-label design with only blinded raters, and the limited scope of pharmacological comparators were noted as key limitations.

Standard TMS for Adolescents with Major Depressive Disorder (MDD)

In 2024, the FDA cleared TMS as a first-line adjunctive treatment for MDD in adolescents aged 15 and older, based on a real-world study of 1,120 patients aged 15–21 treated at 35 U.S. centers (Trapp 2025). Participants completed 36 sessions over approximately 4–6 weeks using either high-frequency deep TMS or iTBS stimulation. The PHQ-9 was administered at baseline and immediately after the treatment course, which showed an average 12-point reduction, a 66% response rate, and notable improvements in anxiety symptoms, with a safety profile consistent with adult TMS use and no new concerns. No long-term follow-up beyond the treatment period was reported.

Croarkin et al (2021) conducted the largest randomized, double-blind, sham-controlled trial to date investigating TMS for TRD in adolescents. The study assessed the feasibility, safety, and efficacy of 10 Hz left prefrontal TMS monotherapy across 13 sites, enrolling 103 participants aged 12 to 21 years who had failed one to four adequate antidepressant trials. Participants were randomized to receive either active TMS (n=48) or sham treatment (n=55) over 30 sessions across six weeks. Treatments were administered using the NeuroStar XPLOR TMS Therapy System (Neuronetics, Inc.), with coil placement guided by the 5-cm rule. Stimulation was delivered at 120% of the resting motor threshold (reducible to 110% for tolerability during the first week), at 10 Hz for 4 seconds per train, with a 26-second intertrain interval, totaling 3,000 pulses per 37.5-minute session. The primary outcome was change in the Hamilton Depression Rating Scale (HAM-D-24) score. Both groups showed similar symptom improvement (P=0.8), with response rates of 41.7% (active) and 36.4% (sham), and remission rates of 29.2% and 29.0%, respectively. No new safety or tolerability concerns were identified. While TMS produced clinically meaningful reductions in depressive symptoms, it did not significantly outperform sham treatment. The authors highlighted the need for future research to address high placebo response rates and refine dosing strategies for adolescents with TRD.

Systematic reviews and meta-analyses have evaluated the efficacy and safety of rTMS in adolescents with MDD. Cao et al (2023) analyzed randomized controlled trials (RCTs) of rTMS combined with antidepressants in children and adolescents, reporting significant improvements in depressive symptoms compared to medication alone, with no major safety concerns. Sun et al (2023) focused on first-episode adolescent MDD and found adjunctive rTMS significantly enhanced treatment response and remission rates versus standard therapy. Sigrist et al (2022) pooled data from 10 individual studies (2 randomized trials) for quantitative synthesis of mainly uncontrolled studies, concluding that rTMS appears well tolerated and associated with a statistically significant overall treatment response rate (p<0.001) from baseline to post-treatment. Though evidence quality is limited by small sample sizes and heterogeneity. All three analyses are limited by small sample sizes,

high statistical heterogeneity, and methodological weaknesses. Overall, authors concluded that rTMS showed significant treatment effect and response rate compared to antidepressants alone, and larger, high-quality trials are needed to establish optimal protocols and long-term safety.

Garzon et al (2025) conducted the largest long-term follow-up study to date. This six-month, multisite, open-label trial evaluated the durability of TMS in adolescents and young adults with TRD. The study enrolled participants aged 12–21 who achieved at least a partial response (≥25% reduction on the Hamilton Depression Rating Scale-24 [HAMD24]) during a prior randomized controlled trial of sham or active TMS. Those experiencing partial relapse (≥1-point increase on Clinical Global Impression–Severity) received retreatment with daily 10 Hz TMS sessions until symptoms returned to baseline or after 30 treatments. Of 84 eligible participants, 66 enrolled and 41 completed the six-month follow-up; 42% required retreatment, with a mean of 22 sessions. At six months, depressive symptoms remained improved (mean HAMD24 = 5.24) compared to baseline at entry into follow-up (mean HAMD24 = 8.21). Higher baseline severity predicted relapse risk, while prior TMS exposure did not. TMS was well tolerated, and the authors concluded that these findings support the feasibility and clinical benefit of a structured retreatment protocol following an initial course of TMS in adolescents with TRD.

Roth et al (2025) conducted the largest naturalistic post-marketing outcomes study to date evaluating the safety and efficacy of deep TMS (dTMS) for MDD in younger populations. The study analyzed data from 1,257 patients treated between January 2012 and November 2024 across 56 geographically diverse clinical sites in the United States. Eligible participants were aged 11–21 years and met criteria for treatment-resistant MDD, having failed to respond to an average of 4.5 antidepressant medications. All patients received dTMS using the BrainsWay H1 Coil (BrainsWay, Jerusalem, Israel), delivered via either the Magstim Rapid2 stimulator (Magstim, Spring Gardens, UK) or the BrainsWay 104 stimulator. Treatment protocols included either 18 Hz or intermittent theta burst stimulation (iTBS), with a mean of 35.6 sessions administered. At baseline, 76% of participants exhibited moderate to severe depressive symptoms (PHQ-9 ≥15). Following treatment, only 16% remained in this severity range, while 65% met criteria for mild or subthreshold depression. Statistically significant improvements were observed across all clinical measures. The treatment was well tolerated, with an adverse event profile comparable to that observed in adult populations. Despite certain limitations, the authors concluded that dTMS represents a safe and effective therapeutic option for adolescents and young adults with treatment-resistant MDD, contributing significantly to the growing empirical support for this therapeutic modality.

Buyuktaskin et al (2025) conducted an exploratory RCT to assess the effects of rTMS frequency on suicidal ideation in adolescents with MDD. Given the elevated suicide risk in youth and limitations of current treatments, including the potential for increased suicidal thoughts with antidepressants, this study compared low-frequency (1 Hz) and high-frequency (10 Hz) TMS protocols. A total of 41 adolescents between the ages of 12 and 18 were randomized to receive either 1 Hz (n=22) or 10 Hz (n=19) TMS, and scheduled for 30 sessions over six weeks, with a mean of 28.00 sessions completed (range: 8–30). Treatment was delivered over the left DLPFC using the NeuroStar system, with localization achieved via the Beam F3 method. Suicidal ideation intensity was measured weekly using the Columbia Suicide Severity Rating Scale (C-SSRS). Over the treatment period, both TMS protocols

were associated with a significant reduction in suicidal ideation intensity, approximately 24.6% for 10 Hz TMS ($p = 0.0015$) and 22% for 1 Hz TMS ($p = 0.0016$), independent of changes in depression severity. However, when adjusting for depression severity, these reductions were no longer statistically significant (10 Hz: $p = 0.572$; 1 Hz: $p = 0.844$). No significant differences were found between the two protocols in their impact on suicidal ideation ($p > 0.7$), and treatment group assignment did not moderate outcomes ($p > 0.95$). The findings suggest that TMS may be a promising intervention for suicidal ideation in adolescent depression, with comparable effects across stimulation frequencies. This study contributes to the growing body of research on TMS as a potentially safe and effective intervention for suicide prevention in adolescents, highlighting the need for further investigation into optimal stimulation parameters.

Accelerated Non-Deep Coil TMS for MDD

Theleritis et al (2017) conducted a single-center, parallel-group, randomized, sham-controlled trial (n=98) to evaluate the efficacy of administering one versus two daily sessions of HF-rTMS for treating MDD. Eligible participants were aged 18–59, right-handed, diagnosed with treatment-resistant nonpsychotic MDD, had no prior exposure to TMS, and were free of contraindications. Where clinically appropriate, participants were encouraged to discontinue antidepressants prior to enrollment; otherwise, they remained on a minimal regimen for at least four weeks before study entry. Treatment involved 10 Hz HF-rTMS using a Magstim Rapid stimulator with a figure-8 coil targeting the left DLPFC. Sessions were delivered on weekdays over three weeks: either once daily (A1 group; n=27) or twice daily (A2 group; n=27), totaling 15 or 30 sessions, respectively. Sham stimulation was administered using a rotated coil either once daily (S1 group; n=20) or twice daily (S2 group; n=24). Response was defined as ≥50% reduction in HDRS and CGI-S ≤3; remission was defined as HDRS <8 and CGI-S ≤2. Assessments were conducted at baseline, weekly during treatment, and at five weeks post-treatment. Nine participants discontinued due to protocol violations, headache exacerbation, scheduling conflicts, or illness. Intent-to-treat analysis (n=96) revealed no significant baseline differences between groups. Active treatment groups showed significantly greater improvements in HDRS and CGI-S scores compared to sham ($p<0.001$). Only one participant (2.5%) in the sham groups met HDRS response criteria, versus 29 (59.2%) in the active groups ($p<0.001$). Remission likelihood was significantly associated with baseline severity ($p=0.001$) and number of daily sessions (CGI-S: $p=0.018$; HDRS: $p=0.066$). Adverse events were mild, including scalp discomfort and headache. Study limitations included lack of blinding for treatment administrators, absence of a sham coil mimicking rTMS sensations, no cognitive assessments, short follow-up, and potential confounding from concurrent pharmacotherapy. Further research is warranted to assess the safety and efficacy of multiple daily rTMS sessions.

Fitzgerald et al (2018) conducted a parallel-group RCT comparing accelerated and standard rTMS protocols in patients with MDD. A total of 115 outpatients were randomized to receive either accelerated rTMS (n=58) or standard rTMS (n=57). Stimulation localization followed standard procedures. Both groups received an equal total pulse dose of 63,000. In the accelerated group, each session involved 83–84 trains of 10 Hz rTMS applied to the left DLPFC using 4.2-second trains at 120% of the resting motor threshold, with 15-second inter-train intervals. Sessions were spaced 15–30 minutes apart, delivering 10,500 pulses per day across six treatment days. In contrast, the

standard group received 20 sessions over four weeks (five sessions per week), each consisting of 75 trains of 10 Hz rTMS with 25-second inter-train intervals, delivering 3,150 pulses per day. The accelerated group showed earlier symptom improvement within the first two weeks, though overall response rates were similar between groups. No serious adverse events occurred, although the accelerated group reported more discomfort and had a slightly higher dropout rate. Cognitive performance remained stable across both groups. Study limitations included short follow-up, lack of blinding, and potential confounding due to session spacing and individual variability in response. Overall, accelerated rTMS delivered over a condensed three-week schedule produced antidepressant effects comparable to standard four-week protocols, with slightly increased treatment discomfort but low dropout rates, supporting the need for larger multisite trials to confirm its clinical utility.

Sonmez et al (2019) conducted a systematic review and meta-analysis to evaluate the efficacy of accelerated TMS protocols for MDD. The review included 18 publications describing 11 unique studies, some with overlapping samples. Studies were eligible if they involved more than one rTMS or TBS session per day and targeted depressive disorders. Three RCTs were included in the meta-analysis, yielding a pooled effect size of Hedges' g = 0.39, indicating a modest but statistically significant antidepressant effect of aTMS compared to control. When open-label studies and active arms of RCTs were analyzed separately, the pooled effect size increased to g = 1.27, suggesting stronger symptom improvement in less controlled settings. The review found that accelerated TMS (aTMS) protocols varied widely in terms of stimulation parameters, coil types, and session spacing. Despite this heterogeneity, most studies reported positive clinical outcomes, with some showing rapid symptom reduction within days. Adverse effects were generally mild and transient, including headache and scalp discomfort. Limitations included small sample sizes, lack of blinding in many studies, and variability in protocol design, which may affect generalizability. The authors noted that many of the included studies had short or limited follow-up periods, which limited the ability to assess long-term efficacy and durability of antidepressant effects from accelerated TMS protocols. Concluding that aTMS is a promising approach for treating MDD, the study emphasized the need for larger, well-controlled trials to establish optimal protocols and confirm efficacy.

Prato et al (2025) conducted a single-center, parallel, two-arm, single-blind RCT in Italy comparing aTMS with the standard rTMS protocol for TRD. The standard protocol consisted of one session per weekday for four weeks, delivering 75 trains of 10 Hz to the left DLPFC at 120% motor threshold per session. The accelerated protocol delivered four sessions per day, separated by one-hour breaks, for five consecutive days, using identical parameters. Both arms were designed to deliver the same cumulative pulse count, 60,000 over 20 sessions, to maintain consistency with foundational rTMS trials. rTMS was delivered using the Magstim Rapid2 stimulator and a 70 mm air-cooled double coil. Participants (ages 18–70) had moderate to severe major depressive episodes (unipolar or bipolar) and were nonresponsive to either fluvoxamine or venlafaxine during the current episode. A total of 33 patients were randomized to aTMS (n = 18) or standard rTMS (n = 15, n=13 after two withdrawals). Clinical outcomes were assessed using the MADRS and Beck Depression Inventory II (BDI-II) at baseline, daily during the first week, weekly through week 4, and at week 8. SSI was measured at baseline, day 1, day 5, and weekly thereafter. Response was defined as ≥50% MADRS reduction; remission as MADRS <10. Analysis included 31 patients (18 aTMS; 13 rTMS). Results

showed a significantly faster decline in MADRS and BDI-II during the first five days (p = 0.001 and p = 0.048, respectively). At day 56, aTMS patients maintained lower scores than rTMS (MADRS: p = 0.001; BDI-II: p = 0.032). Response rates favored aTMS at day 28 (72% vs. 38.5%, p = 0.040) and day 56 (83.3% vs. 38.5%, p = 0.011). Remission rates were also higher for aTMS at day 28 (67% vs. 15.4%, p = 0.0001) and day 56 (61% vs. 30.8%, p = 0.006). No significant differences emerged for suicidal ideation (p = 0.621), and subgroup analysis showed similar benefits for unipolar and bipolar patients. Despite delivering 300 trains per day in the accelerated arm versus 75 in the standard arm, no serious adverse events occurred, and tolerability was comparable. Limitations included small sample size, single-center design, reliance on self-reported measures, and lack of sham control. The authors concluded that aTMS may offer a clinically meaningful advantage by achieving rapid symptom improvement within five days without compromising safety or tolerability, addressing the latency challenge of antidepressant therapy.

Accelerated Deep iTBS for MDD (BrainsWay Deep TMS System)

In 2025, the FDA expanded treatment stimulation protocols for MDD to include accelerated deep iTBS (ad-iTBS) stimulation, delivered by the modified BrainsWay Deep TMS System. Accelerated iTBS was supported by unpublished clinical data from a multicenter, randomized, blinded, controlled study (Protocol No. CTP-ACCiTBS-00). The study was designed as a prospective, 6-week trial, in which the accelerated iTBS stimulation protocol was compared to the standard of care HF stimulation protocol for treating MDD. A total of 104 subjects were enrolled, with 89 completing the study and included in the per-protocol analysis. Participants had moderate or greater depression (HDRS-21 ≥ 20), with a mean age of 48.6 years. The primary endpoint was the change in HDRS-21 scores from baseline to six weeks. Both groups showed significant improvement from baseline to week 6. The between-group difference was non-significant (p = 0.7783), meeting predefined non-inferiority criteria. Common adverse events included headaches and application site pain; none classified as severe. Two subjects discontinued due to anxiety and hypomania. Overall, the study demonstrated that the accelerated iTBS protocol is safe, effective, and non-inferior to the standard high-frequency protocol for MDD treatment.

Bahun et al (2022) reported that accelerated TMS protocols have shown to be as effective as standard rTMS in reducing depression symptoms and achieving remission; however, comparative studies between different accelerated protocols are limited. To investigate whether two- or three-week accelerated deep TMS (a-dTMS) protocols differ in cognitive outcomes, the authors conducted a randomized controlled pilot study in 32 adult psychiatric inpatients with treatment-resistant MDD). Participants (ages 20–70, all on at least one antidepressant) were assigned to receive dTMS twice daily for either two weeks (10 sessions) or three weeks (15 sessions), using the FDA-approved H1-coil protocol targeting the left DLPFC (20-minute sessions, 18 Hz, 120% motor threshold, 1980 pulses per session). Cognitive function was assessed at baseline and post-treatment using a battery of neuropsychological tests. Statistically significant improvements were observed in most cognitive domains, except numeric short-term memory, verbal fluency, and errors on Benton visual retention test (BVRT) and Trail Making Test (TMT). The 3-week protocol showed greater improvement in psychomotor speed, while the 2-week protocol led to significantly better verbal fluency. These findings suggest the shorter protocol may be more efficient and equally or more beneficial in specific

cognitive areas. Limitations of the study include the absence of a control group, small sample size, lack of long-term follow-up, potential placebo effects, use of non-parallel cognitive tests, concurrent pharmacotherapy, and confounding factors such as medication variability and mood-related cognitive changes. The authors concluded that a-dTMS may offer mild to moderate cognitive benefits without adverse effects in TRD patients, but further sham-controlled studies are needed to confirm these findings.

Standard iTBS, without Functional Connectivity MRI

Blumberger et al (2018) conducted the THREE-D trial, which led to U.S. FDA clearance of iTBS for MDD. This multicenter, randomized, non-inferiority study compared high-frequency (10 Hz) rTMS with iTBS for treatment-resistant MDD. A total of 414 participants were randomized to rTMS (n=205) or iTBS (n=209), administered five times per week over 4–6 weeks. Treatment resistance was defined as failure to respond to at least one adequate antidepressant trial or intolerance to two or more trials. Patients who had failed more than three adequate trials were excluded. Participants continued stable antidepressant regimens during the trial, and medication adjustments were permitted. Prior to treatment, all participants underwent high-resolution anatomical MRI, and neuronavigation targeted the left dorsolateral prefrontal cortex using reverse co-registration from the MNI152 coordinate. rTMS sessions lasted 37.5 minutes, whereas iTBS sessions lasted just over 3 minutes. The primary outcome was change in the 17-item Hamilton Rating Scale for Depression (HRSD-17). Both groups showed similar improvements: rTMS (mean reduction: 10.1 points) and iTBS (10.2 points), with an adjusted difference of 0.01, confirming non-inferiority of iTBS. iTBS was associated with slightly higher self-reported pain (mean score: 3.8 vs. 3.4; p=0.011). Headache was the most common adverse event in both groups (rTMS: 64%; iTBS: 65%). Serious adverse events included one myocardial infarction (rTMS) and three psychiatric events (iTBS), with no significant difference in overall adverse event rates. The study did not include a placebo control group. The authors concluded that iTBS is a safe, well-tolerated, and time-efficient alternative to standard rTMS, with comparable clinical effectiveness for treatment-resistant depression.

The 2025 consensus review from the National Network of Depression Centers Neuromodulation Task Group acknowledged that the THREE-D trial employed MRI-guided neuronavigation and a larger B70 figure-8 coil to enhance targeting precision (Trapp 2025). Although these elements are not considered standard clinical practice in the United States and are not required for adherence to the FDA-cleared once-daily iTBS protocol, the clinical efficacy of iTBS has been replicated with protocols that do not utilize neuronavigation guidance and confirmed through meta-analyses of sham-controlled trials.

Accelerated iTBS with Functional Connectivity MRI- (SAINT)

Cole et al (2020) conducted an open-label clinical trial evaluating the Stanford Accelerated Intelligent Neuromodulation Therapy (SAINT) protocol, which uses iTBS guided by functional connectivity MRI (fcMRI) targeting. The study included 21 participants with major depressive disorder. Each participant received 60 cycles of ten bursts of three pulses at 50 Hz, delivered in ten sessions per day (18,000 pulses/day) over five consecutive days. This represents a total pulse dose that is five times greater than the FDA-cleared iTBS protocol (which delivers 18,000 pulses over six weeks).

On average, participants met standard response criteria within 2.3 days of treatment, approximately 23 ten-minute sessions. Despite the small sample size, significant reductions in suicidality was observed, as measured by the Columbia Suicide Severity Rating Scale (C-SSRS) suicidal ideation subscale ($p < 0.001$). The response rate, defined as a ≥50% reduction in depressive symptoms, was 90.48% and all responders achieved remission immediately post-treatment, with 70% maintaining remission at one month. Intent-to-treat analysis showed 86.4% remission, with 80–100% sustained at one-month follow-up. Participants with prior nonresponse to conventional rTMS required more time to respond but 83% achieved response by day five. No adverse events or cognitive impairments were detected on neuropsychological testing. The authors concluded that SAINT appears preliminarily safe, feasible, and associated with high remission rates in treatment-resistant depression, recommending larger randomized controlled trials to confirm these findings.

Cole et al (2022) conducted a double-blind, randomized, sham-controlled trial to assess the antidepressant efficacy of the accelerated Stanford Neuromodulation Therapy (SNT) protocol, also known as the SAINT protocol, combines intermittent theta burst stimulation (iTBS) with individualized targeting based on functional connectivity MRI (fcMRI). The study enrolled 29 participants with major depressive disorder (MDD), randomized to active (n=14) or sham (n=15) treatment groups. Before treatment, all participants underwent structural and resting-state functional MRI to identify individualized stimulation targets using fcMRI. The intervention consisted of 10 daily sessions over five consecutive days, delivering 1,800 pulses per session (18,000 pulses per day) at 90% of the resting motor threshold, adjusted for cortical depth. The trial was stopped early after a planned interim analysis revealed a large effect size (Cohen's $d > 0.8$) favoring active treatment. At four-week follow-up, 79% of active participants (11 of 14) achieved remission compared to 13% (2 of 15) in the sham group. No serious adverse events occurred, though headaches were more frequent in the active arm. Limitations included small sample size, single-site design, and comorbid psychiatric conditions in 45% of participants. The authors concluded that SNT produced significantly greater symptom reduction than sham stimulation and highlighted the need for larger trials to confirm efficacy and clarify the role of fcMRI-guided targeting.

Geoly et al (2025) conducted a prospective observational follow-up study evaluating the durability of response and remission in participants who previously underwent Stanford Neuromodulation Therapy (SNT, also known as SAINT) in open-label or randomized controlled trials conducted by Cole et al (2020, 2022). SNT is an accelerated, high-dose, resting-state functional connectivity–guided intermittent theta burst stimulation (iTBS) protocol that achieves high acute remission rates after five days of treatment; however, durability beyond four weeks without continuation therapy has been unclear. This study included 46 adults with TRD from prior SNT trials (21 open-label, 14 active RCT, 11 sham crossover). Each participant received five days of SNT (10 sessions/day, 18,000 pulses/day at 90% rMT, depth-adjusted) or sham, with individualized targeting of the left dorsolateral prefrontal cortex most anticorrelated with the subgenual anterior cingulate cortex using resting-state fMRI. The 6-item Hamilton Depression Rating Scale (HDRS-6) scores were collected biweekly for up to 24 weeks and relapse was defined as two consecutive HDRS-6 scores ≥5. Results revealed that 70% (32/46) achieved remission the week following treatment and 33% (15/46) remained in remission at 12 weeks. Limitations include small sample size, lack of follow-up beyond 12 weeks, and limited

generalizability due to demographic and clinical characteristics. Findings suggest that SNT's antidepressant effect is durable, with 12-week remission rates comparable to ECT and potentially exceeding acute outcomes of standard iTBS.

Preservation / Maintenance TMS for Adults with Major Depressive Disorder

A variety of maintenance schedules are currently being studied, with the role of maintenance TMS not been fully established and high heterogeneity in administration between studies.

Fitzgerald et al (2013) reported a prospective, open-label trial of clustered maintenance rTMS for patients with treatment-resistant depression. All patients had received a second successful course of rTMS following relapse and were then treated with monthly maintenance therapy consisting of five rTMS treatments over a 2.5-day period (Friday evening, Saturday, and Sunday). Of 35 patients, 25 (71%) relapsed at a mean of 10.2 months (range, 2- 48 months).

Dunner et al (2014) reported one-year follow-up with maintenance therapy from a large, multi-center observational study (42 sites) of rTMS for patients with treatment-resistant depression. A total of 257 of the 307 patients initially studied who were treated with rTMS agreed to participate in the follow-up study. Of these, 205 patients completed the 12-month follow-up, and 120 patients met the Inventory of Depressive Symptoms-Self Report response or remission criteria at the end of treatment. Ninety-three of the 257 patients (36.2%) who enrolled in the follow-up study received additional rTMS (mean, 16.2 sessions). Seventy-five of the 120 patients (62.5%) who met response or remission criteria at the end of the initial treatment phase (including a two-month taper phase) continued to meet response criteria through follow-up.

Two RCTs investigated outcomes of maintenance TMS sessions, concluding that periodic TMS appears feasible in some cases, but once-monthly TMS is not superior to "watchful waiting" (Philip 2016) and rTMS could represent a novel strategy for preventing relapse in treatment resistant depression (Benadhira 2017). Further studies are needed to confirm the benefits of rTMS maintenance and to clarify effectiveness and feasibility.

D'Andrea et al (2023) conducted a systematic review to evaluate maintenance TMS protocols for MDD and TRD. Fourteen studies were included (3 randomized sham-controlled trials, 8 open-label studies, 2 case reports, 1 case series). Most studies suggested maintenance TMS may reduce relapse risk, but protocols varied widely in timing (starting 1 week to 1-month post-acute treatment), duration (12 weeks to >1 year), and structure (cluster, tapering, continuous, rescue), making it difficult to identify optimal parameters. Cluster and continuous approaches appeared to show lower relapse risk, though evidence remains inconclusive. Relapse risk was highest after five months post-acute treatment, and no superiority was observed among left, right, or bilateral DLPFC stimulation. Limitations included small sample sizes (n=1–281), heterogeneity, and risk of bias (3 low, 4 moderate, 3 severe). Overall, despite methodological limitations, the authors concluded that maintenance TMS is a promising strategy to sustain antidepressant effects and reduce relapse, but standardized protocols and high-quality trials are needed.

Yamazaki et al (2023) published a study protocol for a multicenter open-labelled parallel-group trial with a planned recruitment of 300 patients with MDD who have responded or remitted to acute rTMS

therapy. This study aims to evaluate whether maintenance rTMS is effective in maintaining the treatment response in patients with MDD with a large sample size and feasible study design. The protocol of maintenance rTMS therapy is once a week for the first six months and once biweekly for the second six months.

TMS for Adults with Obsessive-Compulsive Disorder (OCD):

Carmi et al (2018) conducted a double-blind pilot study comparing low-frequency deep TMS (LF-dTMS; 1 Hz), high-frequency deep TMS (HF-dTMS; 20 Hz), and sham stimulation in patients with obsessive-compulsive disorder (OCD). A total of 41 adults with a score of 20 or more on the Yale Brown Obsessive Compulsive Scale (YBOCS) were recruited at the Chaim Sheba Medical Center in Israel and randomized to one of three groups to receive one Hz stimulation (LF), 20 Hz stimulation (HF), or a sham stimulation. All participants received five sessions per week for five weeks (25 sessions total). Final analysis included only the HF group (n=16) and sham group (n=14) due to lack of response in the LF group. After five weeks, 43.8% of HF participants (7/16) met predefined response criteria compared to 7.1% of sham participants (1/14). However, at one-month follow-up, significance was lost, with four HF participants and none in the sham group classified as responders. The authors concluded that HF-dTMS is safe, tolerable, and potentially effective for reducing OCD symptoms, but emphasized the need for larger trials. Limitations included small sample size, single-center design, and short follow-up.

Carmi et al (2019) conducted a multicenter randomized double-blind placebo-controlled evaluating HF-dTMS in OCD. A total of 94 eligible patients were randomized to active high-frequency (n=47) or sham (n=47) dTMS for six weeks. Clinical response was assessed using the Yale-Brown Obsessive-Compulsive Scale (YBOCS). At six weeks, Y-BOCS scores decreased significantly in both groups (active: −6.0 points; sham: −3.3 points), with a between-group difference of 2.8 points (p=0.01; effect size = 0.69). Full response rates at follow-up were 45.2% (19/42) for active treatment versus 17.8% (8/45) for sham (p=0.006). Partial response rates were 59.5% vs. 42.2% (p=0.106). Clinical Global Impressions–Improvement (CGI-I) analysis showed 49% of active participants reported moderate to "very much" improvement compared to 21% in sham (p=0.011). CGI-Severity scores also favored active treatment (61% vs. 32.6%; p=0.022). No serious adverse events occurred. Limitations included lack of control for symptom provocation and absence of brain activity recording, limiting mechanistic insights. The authors concluded that HF-dTMS should be considered as an adjunctive treatment for OCD when response to standard psychological or pharmacological interventions is inadequate.

Fitzsimmons et al (2022) conducted a systematic review and pairwise/network meta-analysis to evaluate the efficacy and safety of rTMS as a treatment option for OCD. Eligible studies were peer-reviewed, randomized, sham-controlled trials enrolling patients with a primary OCD diagnosis and delivering any rTMS protocol with at least five treatment sessions. A comprehensive database search through February 2021 identified 21 studies involving 662 participants (368 active rTMS; 294 sham). Across these trials, 11 different stimulation protocols were investigated. The certainty of evidence was rated Moderate, primarily due to potential publication bias. Meta-analysis of post-treatment Yale-Brown Obsessive-Compulsive Scale (Y-BOCS) scores demonstrated a significant improvement with active rTMS compared to sham (Hedges' g = -0.502). Dropout rates did not differ between active and

sham groups. For comorbid depression, scores on the HDRS and MADRS showed a small but statistically significant benefit for active rTMS (g = -0.21); however, due to limited reporting, subgroup and network meta-analyses were not performed for this outcome. CGI-S scores revealed a large and significant improvement favoring active rTMS (g = -0.86). Limitations included missing primary outcome data in three studies, moderate heterogeneity, and variability in methodology (12 different stimulation protocols). The authors concluded that rTMS is an efficacious treatment for OCD, producing an average 4-point reduction in Y-BOCS scores compared to sham, and noted that these findings align with prior systematic reviews and meta-analyses supporting rTMS efficacy for OCD.

Steuber and McGuire (2023) conducted a meta-analysis of RCTs to evaluate the therapeutic benefit of rTMS in patients with OCD and to identify moderators of treatment effects. The analysis included 25 RCTs published through December 2022, encompassing 860 participants. Using a random-effects model, effect sizes for treatment efficacy and response were calculated based on clinician-rated Y-BOCS scores. Across studies, rTMS demonstrated a moderate effect on OCD symptom severity (Hedges' g = 0.65; $p < .001$) and a large effect on treatment response, with response rates of 39.5% for rTMS versus 8.8% for sham conditions ($p < .0001$). Moderator analysis revealed that longer rTMS session duration (in minutes) was associated with greater improvement in OCD severity, accounting for 24% of variance in treatment effects. Conversely, a higher number of rTMS sessions was negatively associated with symptom reduction, explaining 28% of modeled variance. No significant relationship was found between total pulse count and OCD severity reduction. Limitations included diagnostic heterogeneity, exclusion of four RCTs due to missing pre-post data, and lack of long-term follow-up (ranging from 1 to 12 weeks). The authors concluded that rTMS offers a threefold greater likelihood of treatment response compared to sham, and its efficacy, favorable safety profile, accessibility, and potential for treatment-refractory cases suggest rTMS as a promising therapeutic option for OCD, particularly for patients unresponsive to first-line interventions.

Functional Magnetic Resonance Imaging (fMRI) for OCD

Fitzsimmons et al (2024) conducted a blinded, randomized, proof-of-concept trial to evaluate and compare treatment-induced changes in task-based functional magnetic resonance imaging (tb-fMRI) activation following three different repetitive transcranial magnetic stimulation (rTMS) protocols. The study enrolled 61 participants diagnosed with obsessive-compulsive disorder (OCD) resistant to first-line treatments. Participants were randomized into three parallel arms: high-frequency rTMS to the left dorsolateral prefrontal cortex (DLPFC) (n=19), high-frequency rTMS to the left supplementary motor area (preSMA) (n=23), or low-intensity rTMS to the vertex as a control condition (n=19). Each participant received 16 rTMS sessions immediately prior to exposure and response prevention (ERP) psychotherapy over an 8-week period. Task-based fMRI scans and clinical assessments were conducted at baseline (T0), after eight combined rTMS/ERP sessions (4 weeks, T1), after 16 sessions (8 weeks, T2), and at 12 weeks post-treatment (T3). OCD symptom severity was measured using the Yale-Brown Obsessive-Compulsive Scale (Y-BOCS), and depression symptoms were assessed concurrently. Results showed a significant reduction in mean OCD symptom severity across all groups at each time point compared to baseline ($p < .001$), with no significant differences between treatment arms. Depression symptoms also decreased significantly across the entire sample ($p = .0006$) and within each group. ERP adherence, measured by the Patient Exposure and Response

Prevention Adherence Scale, did not differ between groups for homework or in-session exposure exercises. Side effect frequency was similar across groups, and no serious adverse events occurred. The authors concluded that combined rTMS and ERP produced substantial symptom reduction, with 57.4% of participants classified as responders; however, no differences in clinical outcomes were observed between stimulation sites. Limitations included the relatively small sample size, limited number of treatment sessions, short follow-up duration, and insufficient statistical power to detect between-group differences, which restricts the ability to draw firm clinical conclusions.

TMS for Adults with Migraine Headaches:

Saltychev et al (2022) conducted a systematic review and meta-analysis of eight RCTs (n=339 participants) that compared rTMS to sham stimulation in patients with migraine. All RCTs applied high-frequency rTMS to the left dorsolateral prefrontal cortex, and all studies except one included patients with chronic migraine. All studies except one had a low risk of bias and the risk of publication bias was nonsignificant. Results for the frequency of migraine days per month and the intensity of migraine pain both favored rTMS; however, the authors stated that the difference in migraine pain intensity was clinically insignificant.

TMS for Smoking Cessation

TMS to aid in smoking cessation is being investigated as a non-pharmacological treatment option. The evidence is insufficient to determine that the technology results in an improvement in the net health outcome (Li 2020; Shevorykin 2022).

Bellini et al (2024) conducted a double-blind, randomized, sham-controlled trial to test the effect of dTMS on adult smokers. A total of 100 participants were randomized to active (n=50) or sham (n=50) treatment of up to 21 sessions administer over 6 weeks. Participants completed abstinence, mood, and cognition scales at determined timepoints during follow-up. No serious adverse events occurred during this study. Three participants in the active treatment group were withdrawn from the study in the first week for forearm movements during the application of the pulse series. Based on study results the authors concluded that that use of rTMS, with the parameters used and the H4 coil, was not effective in treatment smoking cessation.

Addicott et al (2024) conducted a randomized sham-controlled trial to evaluate the clinical efficacy and safety of administering iTBS for tobacco use disorder, 38 patients received 28 sessions of active (n=25) or sham (n=13) iTBS over 14 visits. Both active and sham groups reported reduced cigarette consumption, cigarette craving, and tobacco withdrawal symptoms. The authors concluded that there were no differences in cigarette consumption between the active and sham iTBS groups, both groups decreased cigarette consumption similarly, and further research is needed to compare iTBS to standard high-frequency rTMS.

TMS for Other Indications

An updated Cochrane Review (Walton 2021) assessed the evidence for use of TMS in individuals with drug-resistant epilepsy compared with other available treatments in reducing seizure frequency, epileptiform discharges, anti-epileptic medication use and side effects, as well as improving quality of life. Eight RCTs (n=241 participants), seven of which were blinded, were included. Two of the studies

showed a statistically significant reduction in seizure rate from baseline (72% and 78.9% reduction of seizures per week from the baseline rate). The remaining six studies did not show a significant reduction in seizure frequency with rTMS compared to controls. Three studies did show a statistically significant reduction in epileptic discharges after active rTMS treatment and adverse events were rare, but an increase in seizure frequency did occur in a small number of individuals. No significant change in medication use was reported. The authors concluded that even though there is reasonable evidence that rTMS is effective at reducing epileptiform discharges, the evidence for the efficacy of rTMS for seizure reduction is low, and further research is needed.

Evidence related to the efficacy of rTMS is limited for other indications. Studies have methodological limitations (e.g., small samples sizes and limited follow-up). The role that TMS has in the treatment of these indications has not yet been established. Alzheimer's disease (Ahmed 2012), amyotrophic lateral sclerosis (ALS) (Fang 2013; Di Lazzaro 2024), anxiety (Trevizol 2021), chronic pain (O'Connell 2018), gambling (Concerto 2023), insomnia (Krone 2023), fibromyalgia (Short 2011; Knijnik 2016; Salychev and Laimi 2017), migraine (Lan 2017), Parkinson's disease (Benninger 2012; Xie 2020; Chen 2021, Zhang 2022), schizophrenia (Matheson 2010; He 2017; Guan 2020; Hua 2022; Johnstone 2022), stroke (Yang 2013; Shen 2022), tinnitus (Peng 2012), Tourette syndrome (Kwon 2011).

Cranial Electrotherapy Stimulation (CES)

Additional evidence is needed to permit conclusions about whether CES improves outcomes for individuals with anxiety or depression. The evidence for depression and anxiety does not support the use of CES. The most direct evidence related to CES for anxiety and depression comes from 5 sham-controlled randomized trials (Barclay 2014; Mishoulon 2015; Lyon 2015; Kim 2021; Morriss 2023) and systematic reviews.

A 2022 meta-analysis by Ching et al. reviewed 11 RCTs (N=794) evaluating CES in patients with anxiety. Anxiety and depressive symptoms were significantly reduced with CES versus control (Hedges' g, -0.625 and -0.648, respectively); however, the analysis is limited by high variability in the number of sessions (14 to 126), session duration (10 to 60 minutes), outcomes scale, and the small number of patients in each trial.

Liu et al (2025) conducted the first meta-analysis of 16 RCT (n=1148) to explore efficacy of CES for primary and secondary depression in adults. Eight trials assessed CES as adjunctive therapy with antidepressants, while others examined CES as monotherapy. Treatment parameters varied widely: stimulation frequency ranged from 0.5 to 15,000 Hz; session duration from 20 to 60 minutes; session frequency from 3 to 7 times per week; and study duration from 2 to 24 weeks. Overall, CES significantly reduced depressive symptoms compared with non-CES treatment, though the effect size was small (Hedges' g = –0.33). CES showed no significant impact on quality of life (g = 0.13). Subgroup analyses suggested greater benefit among females, patients with secondary depression (g = –0.42), and protocols using frequency >100 Hz (g = –0.50), session length ≤30 minutes (g = –0.39), ≤5 sessions per week (g = –0.34), and study duration ≤5 weeks (g = –0.45). The authors concluded CES is an effective, safe, and well-tolerated intervention for reducing depressive symptoms in adults; however, larger, long-term RCTs are needed to confirm efficacy, optimize treatment parameters, and clarify mechanisms within broader mental health contexts.

PROFESSIONAL GUIDELINE(S)

Major Depressive Disorder

The American Psychiatric Association (APA) published a legacy clinical practice guideline, in 2010, for treatment of patient with major depressive disorder supports the use of TMS as a safe and well tolerated treatment in the acute phase.

In 2022, the Department of Veterans Affairs Department of Defense (VA/DoD) issued clinical practice guidelines for the management of MDD.

- A weak recommendation was made for rTMS for treatment for patients who have demonstrated partial or no response to two or more adequate pharmacologic treatment trials.
- The VA/DoD found that there is insufficient evidence to recommend for or against theta-burst stimulation.
- A weak recommendation against choosing Ketamine as an initial pharmacotherapy and for augmentation use of Ketamine for patients with MDD who have not responded to several adequate pharmacologic trials.

In 2025, the Clinical TMS Society (CTMSS) issued a supportive statement for rTMS for the treatment of MDD. Summarizing published evidence, CTMSS concluded that the evidence supports that using rTMS early in the treatment algorithm leads to better treatment outcomes and should be offered to patients after one antidepressant trial that does not result in remission of the depressive episode.

In 2025, an updated consensus review and considerations on TMS to treat depression was endorsed by the National Network of Depression Centers, the CTMSS, and the International Federation of Clinical Neurophysiology (Trapp 2025). Recommendations include:

- A general recommendation that patients receive the full treatment course of 30–36 sessions. There is conflicting evidence about prediction of response after a portion of sessions.
- Although maintenance TMS is promising, the frequency of maintenance treatments needed to sustain benefit is unclear, and larger scale RCT examining efficacy as a function of treatment interval are needed to establish the utility of maintenance protocols.
- Combining psychotherapy with rTMS may have additional benefits, though further research is needed before this is broadly recommended.
- No medication augmentation strategies have enough evidence to be broadly applied, although use of stimulants and glutamate receptor modulators is promising
- Various accelerated protocols are being investigated, and there is some evidence that increased dose (either by number of pulses or number of sessions) is associated with greater antidepressant effect. A novel and FDA-cleared highly accelerated protocol that also incorporates individualized targeting based on functional connectivity has shown high remission rates in an outpatient setting. Larger trials in other settings are underway, and this on-brand protocol only recently became commercially available in April 2024

- Intermittent theta burst stimulation is an FDA-cleared protocol of short duration and is non-inferior to standard high-frequency protocols. Standard high-frequency rTMS and iTBS are equally recommended as an initial antidepressant protocol.

Obsessive-Compulsive Disorder

The APA's legacy practice guideline (2013) for the treatment of patient with OCD states that the overall strength of evidence for somatic therapies (e.g., rTMS) is low and the therapies should be considered only after first- and second-line treatments, and well-supported augmentation strategies have been exhausted.

In 2020, the National Institute for Health and Care Excellence (NICE) published interventional procedures guidance for TMS for OCD, stating that the evidence on the safety of TMS raises no major safety concerns; however, the evidence on efficacy is inadequate in quantity and quality. NICE recommends that TMS should only be used in the context of research.

In 2021, the Clinical TMS Society (CTMSS) issued coverage guidance for TMS for OCD including:

- TMS is reasonable and necessary for a minimum of 29 visits over a 6-week period. Extensions in 2 to 4-week increments are based on clinical need with evidence of response from the first 29 sessions.
- If patients cannot come in five days a week, treatments may be administered three days a week over a longer period of time.
- Retreatment may be considered for patients who met the guidelines for initial treatment and experienced at least a 30% reduction in the YBOCS score, as long as the improvement persisted for at least one month after the prior treatments ended.
- TMS for adolescents with OCD may be appropriate if there is a higher level of treatment resistance. These cases should be reviewed individually for medical necessity and considered a compassionate use.

Theta Burst Stimulation

In 2022, the Clinical TMS Society (CTMSS) acknowledged FDA clearance of the SAINT Neuromodulation System, using the Magnus Medical Saint Neuromodulation System, for treatment-resistant MDD. SAINT differs from conventional iTBS protocols by requiring structural and functional MRI, neuronavigation, and a proprietary algorithm to individualize targeting based on functional connectivity. Whether similar outcomes can be achieved with other devices or standard targeting methods remains unknown and off-label SAINT-like protocols without neuronavigation or targeting methodology consistent with FDA-clearance is unknown

In 2023, the CTMSS issued a statement that iTBS was FDA-cleared for severe MDD based on a non-inferiority study comparing it to a standard 10 Hz TMS, with subsequent studies confirming its efficacy and safety. CTMSS states that there is a clear preponderance of evidence supporting once per day iTBS delivered to left dorsolateral prefrontal cortex (DLPFC) provides comparable acute outcomes to 10 Hz stimulation and should be considered a valid alternative for depression treatment.

Maintenance/Preservation TMS

The 2018 National Network of Depression Centers (NNDC) and APA Council on Research (CoR) consensus recommendations for the application of rTMS found limited evidence regarding maintenance strategies following response or remission with acute rTMS (McClintock 2018). One RCT compared a once-monthly scheduled approach with a re-introduction approach and found that both approaches were approximately equivalent in prolonging clinical benefits. The study also found that "rescue therapy" (re-introduction of daily rTMS triggered by symptom relapse) was effective in 69% of instances.

The Clinical TMS Society (2021) indicates that for patients who demonstrate a late response to TMS, subsequent treatment extensions in ten (10) treatment increments are allowed based on clinical need.

Other Indications

The APA published several clinical practice guidelines to provide evidence-based recommendation for the assessment and treatment of psychiatric disorders. TMS requires further study for use in treating bipolar disorder (2002) and TMS is not addressed in the practice guidelines for borderline personality disorder (2024), eating disorders (2023), schizophrenia (2020), post-traumatic stress disorder (2000), Alzheimer's disease (2000).

The 2018 NNDC and APA CoR consensus recommendation for the application of rTMS reported that there is some evidence of the safe and therapeutic use and clinical benefit of TMS for other neuropsychiatric disorders, but the current evidence is insufficient to support routine clinical rTMS in these populations (McClintock 2018).

In 2023, the Department of Veterans Affairs Department of Defense (VA/DoD) issued clinical practice guidelines for the management of bipolar disorder. A weak recommendation was made to offer rTMS as an adjunctive treatment for individuals with bipolar disorder who have demonstrated partial or no response to pharmacologic treatment for depressive symptoms.

In 2023, the Clinical TMS Society issued coverage guidance (indication, limitations, and medical necessity) for TMS as a treatment for smoking.

REGULATORY STATUS

Devices for TMS have been cleared for marketing by the U.S. Food and Drug Administration (FDA) for the treatment of major depressive disorder in adults who have failed to achieve satisfactory improvement from prior antidepressant medication in the current episode.

The United States Food and Drug Administration (FDA) regulates TMS and CES devices and protocols as medical devices. All TMS and CES devices and protocols require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2025 Nov 3]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most

serious type of recalls. on our website by the date that the FDA posts the information on our website. Available from: https://www.fda.gov/medical-devices/medical-device-safety/medical-device-recalls [accessed 2025 Nov 3]

The U.S. Food and Drug Administration (FDA) has not determined the safety or efficacy of ketamine hydrochloride injection for the treatment of a psychiatric disorder(s) and is considered off-label use for these indications (FDA 2023).

TMS devices have been FDA cleared for the treatment of major depressive disorder (Product Code: OBP), migraine headache pain (Product Code: OKP), obsessive-compulsive disorder (Product Code: QCI), and short-term smoking cessation for adults (Product Code: QMD).

TMS Devices FDA-cleared for Major Depressive Disorder:

Device	Manufacturer	FDA Clearance	Clearance Date
BrainsWay Deep TMS System with accelerated iTBS protocol	BrainsWay	K251449	09/13/2025
BrainsWay Deep TMS System	BrainsWay	K222196	05/31/2025
NeuroStar Advanced Therapy System *ages 15-21	Neuronetics	K231926	03/22/2024
Horizon 3.0 TMS Therapy System	Magstim	K222171	01/13/2023
Magnus Nueromodulation System with SAINT Technology	Magnus Medical	K220177	09/01/2022
ALTMS Magnetic Stimulation Therapy System	REMED Co., Ltd	K220625	04/06/2022
MagVenture TMS Therapy	Tonica Elektronik	K193006	08/09/2020
Horizon TMS Therapy System with iTBS protocol	Magstim	K182853	03/15/2019
Mag Vita TMS Therapy System with Theta Burst Stimulation	Tonica Elektronik	K173620	8/14/2018
Apollo TMS Therapy System *age 15 and older	Magstim	K180313 K243700	05/04/2018 09/04/2025
Nexstim	Magstim	K171902	11/10/2017
Horizon	Magstim	K171051	09/13/2017

- Code list may not be all inclusive (AMA and CMS code updates may occur more frequently than policy updates).
- (E/I)=Experimental/Investigational
- (NMN)=Not medically necessary/appropriate

CPT Codes

Code	Description
0889T (E/I)	Personalized target development for accelerated, repetitive high-dose functional connectivity MRI–guided theta-burst stimulation derived from a structural and resting-state functional MRI, including data preparation and transmission, generation of the target, motor threshold–starting location, neuronavigation files and target report, review, and interpretation
0890T (E/I)	Accelerated, repetitive high-dose functional connectivity MRI–guided theta-burst stimulation, including target assessment, initial motor threshold determination, neuronavigation, delivery and management, initial treatment day
0891T (E/I)	subsequent treatment day
0892T (E/I)	subsequent motor threshold redetermination with delivery and management, per treatment day
0997T (E/I)	Precuneus magnetic stimulation; treatment planning using magnetic resonance imaging-guided neuronavigation to determine optimal location, dose, and intensity for magnetic stimulation therapy, derived from evoked potentials from single pulses of electromagnetic energy recorded by 64-channel electroencephalogram, including automated data processing, transmission, analysis, generation of treatment parameters with review, interpretation, and report (effective 01/01/26)
0998T (E/I)	Precuneus magnetic stimulation; personalized treatment delivery of magnetic stimulation therapy to a prespecified target area derived from analysis of evoked potentials within the precuneus, utilizing magnetic resonance imaging-based neuronavigation, with management, per day (effective 01/01/26)

PRODUCT DISCLAIMER

- Services are contract dependent; if a product does not cover a service, medical policy criteria do not apply.
- If a commercial product (including an Essential Plan or Child Health Plus product) covers a specific service, medical policy criteria apply to the benefit.
- If a Medicaid product covers a specific service, and there are no New York State Medicaid

guidelines (eMedNY) criteria, medical policy criteria apply to the benefit.

- If a Medicare product covers a specific service, and there is no national or local Medicare coverage decision for the service, medical policy criteria apply to the benefit.

POLICY HISTORY/REVISION	
Committee Approval Dates	
New: 01/19 **Revised**: 10/21, 12/21, 10/23, 10/24, 12/24, 6/26 **Reviewed**: 01/21, 12/22, 12/23	
Date	**Summary of Changes**
6/2026	• Transitioned Transcranial Magnetic Stimulation (TMS) policy, 1370/20.000496 to Lifetime HealthCare Companies policy template.
12/2024	• Updated Medicare product variation to "subject to all terms and conditions noted above in the policy".
10/2024	• Added criteria for repeat TMS treatment: must have a 3-month gap in treatment. • Added verbiage that maintenance/continuation TMS treatment is not covered.
10/1/2023	• Added NPPs to policy as providers that can perform TMS, as per CMS.
1/1/2022	• Updated link in resources for source #4. • Updated criteria used to make medical necessity determinations • Criteria for Medicare is listed independently.

MEDICAL POLICY

Medical Policy Title	**Transendoscopic Therapies for Gastroesophageal Reflux Disease (GERD)**
Policy Number	**7.01.45**
Current Effective Date	**September 1, 2026**
Next Review Date	**March 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. The following transendoscopic procedures are considered **investigational** for the treatment of gastroesophageal reflux disease (GERD):

A. Thermal energy-based antireflux therapies applied to the gastroesophageal junction (e.g., Stretta procedure, anti-reflux mucosal ablation [ARMA]);

B. Endoscopic gastroplasty;

C. Endoscopic gastroplication (e.g., GERDx-System, Apollo OverStitch, EndoCinch, Syntheon ARD Plicator);

D. Transoral incisionless fundoplication (TIF) (e.g., EsophyX, MUSE);

E. Injection or implantation of biocompatible bulking agents (e.g., polymethylmethacrylate [PMMA] or plexiglas beads, Durasphere).

DESCRIPTION

Gastroesophageal reflux disease (GERD) is a prevalent condition characterized by classic symptoms such as heartburn and regurgitation, as well as other manifestations including chest discomfort, dysphagia, and chronic cough or throat clearing. While many individuals experience episodic reflux symptoms, a subset develops chronic GERD that increases the risk of complications such as erosive esophagitis, dysphagia, Barrett esophagus, and asthma.

The pathophysiology of GERD is multifactorial. Excessive acid exposure to esophageal mucosa may

occur due to dysfunction of the lower esophageal sphincter, impaired diaphragmatic support of the gastroesophageal junction, or abnormalities in esophageal clearance mechanisms. Delayed acid clearance increases the duration of exposure and enhances the potential for mucosal injury.

Current guideline-based management emphasizes a stepwise approach beginning with lifestyle modification (e.g., weight loss, smoking cessation, head of bed elevation, elimination of food triggers) and pharmacologic therapy such as antacids and proton pump inhibitors (PPIs).

For patients who continue to experience symptoms despite optimized medical therapy, or for whom procedural intervention is clinically appropriate, antireflux surgical and transesophageal endoscopic therapies may be considered. Nissen fundoplication, the most commonly performed antireflux procedure, reinforces the lower esophageal sphincter by wrapping a portion of the gastric fundus around the distal esophagus and, when indicated, concurrently repairing an associated hiatal hernia to restore normal anatomy.

Transesophageal endoscopic therapies have emerged as minimally invasive alternatives to long-term pharmacologic management or laparoscopic. These procedures, considered forms of natural orifice transluminal endoscopic surgery (NOTES), generally fall into three categories:

- Energy-based therapies. The Stretta procedure delivers controlled RF energy to the lower-esophageal sphincter (LES)/gastroesophageal junction (GEJ) and appears to modulate neuromuscular function, reduce transient LES relaxations, and decrease GEJ compliance. The precise mechanism remains uncertain. Anti-reflux mucosal ablation (ARMA) uses thermal mucosal ablation (e.g., electrocautery in spray coagulation mode) of the gastric cardia to induce fibrosis and tighten the GEJ.
- Endoluminal/endoscopic GEJ-reshaping procedures (e.g., mechanical plication, mucosal resection/remodeling, hybrid techniques) are designed to recreate a functional valve and reinforce the antireflux by folding or fastening the fundus or by inducing mucosal fibrosis/scar remodeling. Devices examples include Medigus Ultrasonic Surgical Endostapler (MUSE), GERDx-System, StomaphyX, Apollo Overstitch, Captivator EMR Device).
- Transoral incisionless fundoplication (TIF), also referred to as endoluminal fundoplication (ELF), reconstructs the gastroesophageal valve and reinforce the antireflux barrier using a specialized device passed transorally under endoscopic visualization. Gastric fundus tissue is drawn into a shaping mold and secured with polypropylene fasteners to create a 3–5 cm partial fundoplication without external incisions.
- Injection or implantation of a prosthetic or bulking agent is used to increase tissue bulk at the LES and reduce reflux. These materials are intended to augment the antireflux barrier by improving closure of the sphincter.

SUPPORTIVE LITERATURE

The evidence is insufficient to determine that transesophageal endoscopic therapies for the treatment of GERD (e.g., application of radiofrequency energy, gastroplication, TIF, and injection/implantation of prosthetic devices or bulking agents) results in an improvement in the net health outcome. Large-

scale, long-term controlled studies of these transendoscopic techniques are needed to establish the safety and efficacy of these procedures.

Meta-Analyses Comparing Multiple Antireflux Procedures

Yao et al (2024) conducted a systematic review and network meta-analysis to assess the efficacy of various antireflux interventions when compared to a control group of either PPIs or sham. A total of 19 randomized controlled trials (RCTs) (n=1181 subjects) met inclusion criteria. Four RCTs compared endoscopic band ligation (EBL; n=306 cases); 6 RCTs compared Stretta (235 cases); 5 RCTs compared TIF (340 cases), 2 RCTs compared endoscopic full-thickness plication (EFTP) (214 cases), and 2 RCTs compared EndoCinch (86 cases). This network meta-analysis found that TIF was significantly inferior to PPIs, EFTP, and EndoCinch in decreasing acid exposure. EBL was not inferior to TIF in improving GERD symptoms. The effect of EBL in increasing the LES pressure and improving acid exposure could not be concluded given that no relevant data were provided in the 4 RCTs involved. EBL and TIF may achieve equivalent efficacy in improving the Health-Related Quality of Life (HRQL) score and decreasing the incidence of esophagitis and PPIs utility in patients with GERD, and both may be superior to control and other types of endoscopic interventions. TIF may significantly increase the LES pressure and was superior to Stretta and EndoCinch. The mechanism of Stretta in GERD therapy remains a mystery, has not yet been fully clarified, and more studies are required. The authors concluded that given the limited number of included RCTs on different types of endoscopic treatments, indirect comparison, and inherent heterogeneity, the analysis results should be interpreted with caution. More well-designed and prospective multicenter RCTs with long-term follow-up are required to evaluate the long-term efficacy and safety of different endoscopic minimally invasive interventions in the treatment of GERD.

Tade et al (2025) conducted a meta-analysis of randomized and cohort studies (1980–2024) including adults with GERD who underwent fundoplication (Nissen, Toupet), magnetic sphincter augmentation (MSA), or transoral incisionless fundoplication (TIF). The analysis pooled 9,516 patients with available pre- and post-operative acid exposure time (AET), DeMeester score, and/or symptom relief scores (e.g., GERD-HRQL); the median follow-up was 12 months. Across procedures, AET, DeMeester scores, and symptom relief improved significantly. In multilevel meta-regression, TIF showed significantly less improvement than Nissen in AET ($p = 0.045$) and DeMeester ($p = 0.023$), while MSA and Toupet demonstrated significantly better symptom relief than Nissen (MSA $p = 0.044$; Toupet $p = 0.034$). The authors noted study-level heterogeneity and limitations, including incomplete data on hiatal hernia characteristics/repair techniques and procedural variations, and they did not meta-analyze postoperative complications (e.g., dysphagia, bloating) as primary outcomes. Overall, Nissen fundoplication demonstrated significantly better improvement with acid exposure and DeMeester score compared to MSA and TIF. However, symptom relief scores are significantly improved with Toupet fundoplication and MSA compared to other surgical treatment options.

Endoscopic Energy-Based Therapies

Kalapala et al (2017) published interim results from a small RCT of 20 patients randomized to PPI plus Stretta or PPI alone, with 3 months of follow-up. While short-term outcomes such as GERD symptoms and cessation of PPIs appeared improved for the Stretta group, the study sample was

small, and power calculations were not conducted.

Ma et al (2020) reported on a retrospective comparison of laparoscopic Toupet fundoplication with the Stretta procedure. The two groups were comparable at baseline in demographic characteristics, body mass index, GERD family history, and comorbid hypertension, coronary disease, and diabetes. Two patients in each group were lost to follow-up and excluded from the final analyses. At 12 months, there were no statistically significant differences between the laparoscopic Toupet fundoplication and Stretta groups in GERD relapse. However, compared to laparoscopic Toupet fundoplication, the Stretta group had a high DeMeester score (8.8 vs. 7.3; $p<.05$) and less LES pressure. Important limitations of this study are its single-center design and short follow-up time.

Zerbib et al (2020) published a double-blind RCT that compared Stretta plus proton pump inhibitor (PPI) therapy (n=29) to sham plus PPI therapy (n=33) in individuals with PPI-refractory heartburn from eight French centers. The primary endpoint was clinical success at week 24, defined as an intake of fewer than 7 PPI doses over the previous 2 weeks and adequate subjective patient-reported symptom control. Fewer patients achieved the primary endpoint in the Stretta group, but the difference was not statistically significant. Severe adverse events were more frequent in the Stretta group (7 vs. 2) and included epigastric pain (n=3), delayed gastric emptying, vomiting, headache, and 1 leiomyoma. Limitations of this RCT include that pH-impedance monitoring was not performed either at enrollment or during follow-up. Thus, baseline status of GERD diagnosis is unclear, and the physiologic effects of Stretta are unknown.

Xie et al (2021) published a systematic review and network meta-analysis of ten RCTs (n=516 participants) that evaluated the comparative effects of Stretta, TIF, and PPIs in patients with GERD. Of the included RCTs, five compared Stretta to control (PPI or sham + PPI) and five compared TIF to control (PPI or sham + PPI). Results of the network meta-analysis revealed that improvements in the health-related quality of life score induced by Stretta were not significantly different than the improvements seen with TIF; however, both Stretta and TIF were significantly superior to PPIs. Additionally, both Stretta and TIF were significantly better than PPIs at improving heartburn scores. With regard to reduction in PPI use and esophagitis incidence, no significant differences between TIF and Stretta were observed. This network meta-analysis had several limitations including a lack of assessment of long-term efficacy, the small number of studies, and lack of RCTs directly comparing Stretta and TIF, some comparisons were significantly affected by heterogeneity, and the evidence quality of each outcome ranged from moderate to very low.

Endoluminal/Endoscopic GEJ-Reshaping Procedures

Weitzendorfer et al (2018) conducted a prospective single-center one-arm trial on the clinical and functional outcomes of endoscopic full-thickness plication with GERDx-system. The study included 40 adult patients with at least one typical reflux symptom despite treatment with a PPI for at least 6 months, pathologic esophageal acid exposure, endoscopic Hill grade II–III, a hiatal hernia measuring < 2 cm and excluded individuals with Barrett's esophagus or esophageal motility disorders. Outcomes measured Evaluation of Gastrointestinal Quality of Life Index (GIQLI), symptom scores, esophageal manometry, and impedance-pH monitoring which were performed at baseline and at three months after surgery. Although 30 participants (75%) reported symptomatic improvement, the authors noted

grade A esophagitis persisted or recurred in about one-third of patients. Only 19 patients (63.3%) were off medication after application, which the authors report is similar to other endoscopic procedures like MUSE and Esophyx. The study was limited by the lack of randomization, small sample size, and the necessity of high operator expertise needed to achieve a good procedure outcome. Long-term outcomes are required to expand our knowledge of the effects of this procedure.

Kalapala et al (2022) published results of a randomized, sham-controlled, single-blinded clinical trial using a new endoscopic full-thickness fundoplication device, the GERD-X. A total of 70 individuals with PPI-dependent GERD were randomized to either GERD-X treatment or a sham procedure. The primary end point was ≥ 50% improvement in GERD-HRQL score at 3 months. This outcome was more frequently achieved in the GERD-X group vs. sham (65.7% vs 2.9%; p<0.001). In the GERD-X group, 62.8% of subjects were off-PPI at 12 months compared with 11.4% in the sham group (p<0.001). Overall, the procedure using the GERD-X device was found to be effective at reducing GERD symptoms and improving quality of life. However, in this small, short-term study, reflux was not assessed objectively at the end of 12-month follow-up in all subjects. The authors concluded that large, prospective trials with long-term follow-up are required to conclude the benefits of this procedure after 1 year.

Liu et al (2019) evaluated the short-term efficacy of clip band ligation anti-reflux therapy (C-BLART), a new alternative endoscopic treatment for controlling GERD symptoms, esophageal acid exposure, esophagitis, and quality of life. Patients with refractory GERD were recruited for a nonrandomized concurrent comparison, with 60 patients in the C-BLART with tailored PPI use group and 43 patients in the BID proton pump inhibitor (PPI) group. Crossover from the BID PPI group to the C-BLART with tailored PPI use group was allowed after 6 months. The LES pressure and GERD-Q score improved more in the C-BLART with tailored PPI use group ($P < 0.001$) after 6 months, with no significant difference in the decrease in esophagitis compared with the baseline endoscopic results ($P = 0.268$). Treatment with PPIs had been halted in 43% of the patients at 6 months after C-BLART. At 12 months after C-BLART, the DeMeester score showed a significant improvement compared with the baseline measurements ($P = 0.025$). The GERD-Q score and LES pressure did not significantly improve compared with the baseline values ($P = 0.102$, $P = 0.184$) in C-BLART with tailored PPI use group. At 6 to 12 months, $n = 6$ (10%) patients had undergone laparoscopic fundoplication to control their symptoms in all the patients after C-BLART. The authors concluded that C-BLART is a novel treatment for controlling refractory GERD symptoms, esophageal acid exposure, and LES pressure according to this short-term analysis, safely performed endoscopically to create an anti-reflux barrier with ligated bands. Despite improvements in DeMeester score, LES pressure, and GERD-Q scores in the C-BLART with tailored PPI use group, many patients continue to demonstrate objective evidence of GERD.

Antireflux Mucosal Interventions

Al-Obaidi (2025) conducted a systematic review and meta-analysis that evaluated the efficacy of antireflux mucosal ablation (ARMA) and antireflux mucosectomy (ARMS). The meta-analysis included studies reporting pre- and post-procedure esophageal 24-hour pH monitoring following ARMA and ARMS. Based on pooled data from three studies, ARMA demonstrated a significant post-procedure decrease in median acid exposure time (AET) with a standardized mean difference of -20.74 (p <

0.0001). Based on six studies, ARMS showed a significant reduction in DeMeester score (SMD: -2.79, $p < 0.0001$). The overall clinical success rate, defined as significant symptom improvement or reduced reliance on proton pump inhibitors, was 87% for ARMA and 78% for ARMS. The authors concluded that both procedures displayed promising efficacy in improving GERD-related outcomes, though they noted high heterogeneity suggesting further research is needed to identify patient-specific factors influencing treatment response.

Transoral Incisionless Fundoplication (TIF)

Current evidence is insufficient to determine the effect of this intervention on the net health outcome in patients whose symptoms are adequately controlled by PPIs.

Trad et al (2015; 2017; 2018) conducted TEMPO, prospective, randomized, multicenter trial comparing TIF 2.0 (n=40) with maximal-dose PPI therapy (n=23), with the primary endpoint of symptom elimination. At 6 months (pre-crossover), TIF eliminated troublesome regurgitation significantly more often than PPIs (97% vs 50%, $p = 0.006$), whereas pH normalization rates were not significant between groups (54% off PPI after TIF vs 52% on PPI in the control arm; $p = 0.914$). By the 3-year follow-up, all patients in the control group had crossed over to TIF and were included in the follow-up. Among 63 TIF-treated patients, 83% had available data on PPI use, with 71% reporting cessation, and 77% had evaluable symptom and pH data, showing pH normalization in 40% and resolution of troublesome regurgitation in 90%. At 5 years, follow-up data were available for 44 patients, of whom 86% continued to show elimination of troublesome regurgitation, 34%–43% were completely off PPIs, and GERD-HRQL scores remained improved with high satisfaction. No serious adverse events were reported, and 3 reoperations occurred over 5 years. Overall, the long-term results suggest that TIF provides durable improvement in regurgitation symptoms with moderate rates of PPI discontinuation, supporting its use in selected GERD patients seeking a minimally invasive alternative to medical therapy.

Testoni PA et al (2015 and 2019) published sequential prospective single-center cohorts evaluating the long-term durability of TIF using the EsophyX device. The 2015 study reported outcomes in 50 patients (51 procedures) followed for up to 6 years, with technical success in 48/50 and severe complications in 2/51 procedures. Patients experienced significant early improvement in GERD-HRQL, regurgitation scores, and PPI dependence. The subsequent 2019 study extended follow-up and demonstrated that the improvements in GERD-HRQL observed at 2 years were maintained without substantial decline through the 10-year period; however, at 10 years, only 14 patients had evaluable follow-up, which limits generalizability of the apparent durability. The proportions of patients who discontinued or halved PPI therapy were 86.7%, 84.4%, 73.5%, 83.3%, and 91.7% at 2, 3, 5, 7, and 10 years, respectively. Non-responders (n=7) ultimately underwent surgical fundoplication, and some patient attrition occurred over time. These findings suggest that symptom control and reduced PPI use can be maintained long-term (6-10 years) after EsophyX-based TIF in selected patients; however, the single-arm observational design, modest sample size, and loss to follow-up limit generalizability.

Richter et al (2018) performed a systematic review and network meta-analysis of RCTs completed through May 2017 to compare the relative efficacies of TIF and laparoscopic Nissen fundoplication

(LNF) in GERD. Across seven trials (n=1,128 patients), LNF demonstrated the highest probability of improving physiologic GERD parameters, including increased LES pressure and reduced esophageal acid exposure. TIF ranked below LNF and PPIs on most objective measures, and the authors concluded that LNF is superior to TIF and PPIs for improving physiologic parameters of chronic GERD, including increased LES pressure and decreased percent time pH. TIF was not recommended as a long-term alternative to PPI or LNF treatment of GERD, as long-term efficacy has not been demonstrated.

Chimukangara et al (2019) performed a single-center, retrospective cohort study evaluating long-term outcomes in 57 patients who underwent TIF (EsophyX) between 2007 and 2014 at a large academic medical center. All patients had symptomatic GERD and were taking a PPI at least daily. Patients were excluded for hiatal hernia > 2 cm, LA grade C or D esophagitis, or biopsy-proven Barrett's esophagus. Reflux symptoms and GERD-HRQL were assessed at baseline, short-term (median 12 months, n=36), and long-term (median 97 months, n=23) follow-up. Twelve patients (21%) underwent subsequent laparoscopic antireflux surgery during follow-up, including five within the first year. GERD-HRQL improved from 24 at baseline to 7 at short-term and 10 at long-term ($p < 0.01$ for both). Dissatisfaction with symptom control decreased from 100% at baseline to 26% at long-term. While most patients were on twice-daily PPI therapy pre-TIF, 73% of those who resumed PPIs long-term were on daily PPI therapy (20 mg or 40 mg). The study is limited by its retrospective design, small sample size, single-institution setting, and lack of a matched LARS comparison group. The authors concluded that TIF can provide durable improvements in disease-specific quality of life for some patients with GERD, although many resume antisecretory medications long-term, and most report ongoing satisfaction with symptom management.

Testoni SGG et al (2021) published a systematic review and meta-analysis examining long-term outcomes (≥ 3 years) after TIF performed with the EsophyX device, with outcomes including patient satisfaction, QoL, and PPI use. Among the 8 included studies (n=418; only one open-label RCT) the mean follow-up was 5.3 years, and many patients reported symptom improvement and reduced PPI use, with pooled satisfaction increasing from 12.3% pre-procedure to 70.6% post-procedure, 53.8% completely off PPIs and 75.8% off or on only occasional PPIs at long-term follow-up, mean GERD-HRQL improving from 26.1 to 5.9 (off PPIs), and normalization rates of 73% for heartburn and 86% for regurgitation. The analysis was limited by marked heterogeneity and the predominance of non-controlled designs (only one open-label RCT). The authors conclude that TIF appears to be a safe long-term option for selected patients who decline or cannot tolerate prolonged PPI therapy or surgery.

Testoni SGG et al (2022) conducted a prospective, single-center observational study evaluating the clinical, functional, and endoscopic effects of TIF performed with the MUSE device in 46 adults with chronic (≥ 6 months) GERD symptoms, partial or complete response to PPI therapy, non-erosive reflux disease (NERD) or hypersensitive esophagus, Barrett's esophagus < 3 cm, and BMI < 40 kg/m^2. TIF was successfully completed in 45/46 cases, with two perforations requiring surgery (4.4%) and one additional patient undergoing Nissen fundoplication within 6 months for lack of efficacy, after which these patients were excluded from follow-up analyses. The study showed significant symptom improvement with PPI cessation in 64.3%, 62.9%, and 74.2% of patients at 1,

2, and 3 years (corresponding ITT rates 58.7%, 56.4%, 65.7%), and ≥ 50% reductions in GERD-HRQL and Reflux Symptom Index (RSI) scores were sustained through 3 years; however, esophagitis persisted in about one-third of patients at 1 year, and improvements in pH-impedance observed at 6 months were not maintained at 1 year, although high-resolution manometry (HRM) at 6 months showed increases in LES length and peristaltic waves. The authors note limitations including small sample size, inclusion limited to mild (grade A) esophagitis, lack of a control group, and the need for larger randomized trials with longer-term follow-up.

Canto et al (2025) conducted a prospective, multicenter cohort registry study across nine academic and community centers enrolling adults with confirmed GERD, body mass index <35 kg/m², and hiatal hernia < 2 cm who underwent TIF 2.0. Primary outcomes were safety and clinical success (defined as response in 1 subjective and at least 1 of 3 objective secondary endpoints), and secondary outcomes included symptom improvement, esophageal acid exposure time (AET), esophagitis healing, proton pump inhibitor (PPI) use, and satisfaction. Patients completed surveys and postprocedure adverse assessments at 1-, 6-, and 12-months. Of 85 patients treated, 81 were included in the analysis. Clinical success was achieved in 94%, GERD-Health-Related Quality of Life improved in 89%, Reflux Symptom Index normalized in 85% of those with elevated baseline, patient satisfaction increased from 8% to 79% (P<.0001), and daily PPI use decreased from 81% at baseline to 80% on no or occasional PPI after TIF 2.0 (P<.0001). AET normalized in 72% overall and was more likely when an optimized TIF 2.0 valve (> 300° circumference and > 3-centimeter length) was achieved (94% vs 57%; P=.007). No TIF 2.0-related serious adverse events were reported. The authors conclude that TIF 2.0 is a safe and effective outpatient endoscopic option for appropriately selected patients with GERD. Larger prospective studies of long-term outcomes, particularly for concomitant hiatal hernia repair with TIF (cTIF), are needed to compare safety, effectiveness, and durability with surgical antireflux approaches.

Prosthetic or Bulking Agents

High-quality data from large RCTs are needed to compare bulking procedures with both sham controls and with the currently accepted treatments for GERD (i.e., drug therapy, laparoscopic fundoplication) to determine the effects on health outcomes.

The available evidence for Durasphere consists of a single case series. One open-label pilot study by Ganz et al (2009) assessed ten patients diagnosed with GERD and injected with Durasphere (Carbon Medical Technologies). At 12 months, seven patients (70%) discontinued all antacid medication completely. No erosion, ulceration, or sloughing of the material was noted at any injection site.

The available evidence for polymethylmethacrylate beads consists of a single case series that evaluated transesophageal submucosal implantation of polymethylmethacrylate beads in ten patients with GERD who were either refractory to or dependent on PPIs (Feretis 2001). While a significant decrease in symptom scores was noted at posttreatment follow-up (time not specified), the small number of patients and lack of long-term follow-up precluded scientific analysis.

PROFESSIONAL GUIDELINE(S)

In 2025, the American Society for Gastrointestinal Endoscopy (ASGE; Desai) published updated

guidelines on the diagnosis and management of gastroesophageal reflux disease (GERD). In patients with GERD symptoms, the ASGE made a strong recommendation for lifestyle modification (e.g., dietary changes, weight loss when indicated, head-of-bed elevation), and medical management with PPIs at the lowest dose for the shortest duration. Recommendations for endoscopic therapies include:

- Conditional recommendation: Transoral incisionless fundoplication (TIF) may be considered as an alternative to chronic medical management for patients with confirmed GERD, small hiatal hernia (≤ 2 cm), Hill grade I or II, and any of the listed criteria (including GERD ≥ 6 months, chronic PPI use ≥ 6 months, refractory GERD, regurgitation-predominant GERD patient preference for avoidance of long-term PPI use).
    - Overall, the certainty in the evidence was moderate to very low. TIF 2.0 showed short-term improvement with durable symptom remission up to 5 years with relatively low serious adverse event rates.
- Conditional recommendation: Combined hiatal hernia repair with TIF (cTIF) may be considered for patients with large hiatal hernia (> 2 cm) and Hill grade III or IV, in a multidisciplinary review.
    - Overall, the certainty of the evidence was very low. The panel considered the evidence as important but inadequate. Evidence for surgical therapies has been established and whether cTIF is comparable is not yet established with high-quality data.
- Best practice advice: Radiofrequency energy to the lower esophageal sphincter (e.g., Stretta) may be considered when other alternatives (e.g., endoscopic, or surgical fundoplication) are not available or feasible.
    - Overall, the certainty in the evidence was low to very low. The panel acknowledged that evidence on Stretta has been affected by differing results from RCTs and cohort studies. Existing challenges include lack of durable benefit, no effect on PPIs, no effect on acid exposure, higher adverse events, better available treatments. Stretta is only applicable for GERD patients with small hiatal hernias (≤ 2 cm) and Hill grade I or I.
- No recommendation for or against the following novel endoscopic antireflux therapies due to insufficient controlled long-term data: endoscopic full-thickness fundoplication (EFTP) using device GERDxTM, MUSE, antireflux mucosectomy (ARMS), antireflux mucosal ablation (ARMA).

Slater et al (2023) published a multi-society consensus guideline with recommendations on the treatment of GERD. The panel suggests that adult patients with GERD may benefit from:

- Either MSA or Nissen fundoplication based on surgeon and patient shared decision making. (Conditional recommendation, very low certainty of evidence).
    - The panel judged that the desirable and undesirable effects were balanced and thus favored neither MSA nor Nissen fundoplication.
- Fundoplication over TIF 2.0 (Expert Opinion recommendation; Grade recommendation was unable to be determined due to lack of evidence).

  - The low level of worldwide adoption of endoscopic treatment with TIF 2.0 is correlated with lack of sufficient comparative trials.
- TIF 2.0 over continued PPI (Conditional recommendation, moderate certainty of evidence).
  - TIF 2.0 is an intervention for those who want to avoid both traditional surgery and lifelong medication. Additional long-term prospective comparative studies of TIF (and especially combined laparoscopic hiatal hernia repair and endoscopic TIF) versus fundoplication (partial fundoplication in particular) are needed.
- Fundoplication over Stretta (Conditional recommendation, very low certainty of evidence).
- Stretta over PPI (Conditional recommendation, low certainty of evidence).
- Partial fundoplication compared to complete fundoplication. (Conditional recommendation, moderate certainty of evidence).

In 2022, the American Gastroenterological Association (AGA) issued a clinical practice update on the personalized approach to the evaluation and management of GERD (Yadlapati 2022). The guideline states "transoral incisionless fundoplication is an effective endoscopic option in carefully selected patients" with proven GERD. The guideline further stated that TIF has "demonstrable value in patients with regurgitation-predominant GERD" and that "further research into risks/benefits, durability, effectiveness, and treatment outcomes will enhance optimal utilization" as part of a personalized approach to treatment.

In 2022, the American College of Gastroenterology (ACG) issued guidelines on the diagnosis and management of GERD include the following recommendations for surgical and endoscopic options for GERD (Katz 2022):

- Recommend consideration of magnetic sphincter augmentation (MSA) as an alternative to laparoscopic fundoplication for patients with regurgitation who fail medical management. (Strong, moderate level of evidence)
- Suggest consideration of Roux-en-Y gastric bypass (RYGB) as an option to treat GERD in obese patients who are candidates for this procedure and who are willing to accept its risks and requirements for lifestyle alterations. (Conditional, low level of evidence)
- No recommendation for radiofrequency energy (Stretta) as an alternative to medical or surgical antireflux therapies since data on the efficacy is inconsistent and highly variable. (Conditional, low level of evidence)
- Suggest consideration of TIF for patients with troublesome regurgitation or heartburn who do not wish to undergo antireflux surgery and who do not have severe reflux esophagitis or hiatal hernias > 2 cm. (Conditional, low level of evidence)

Gawron et al (2020) published recommendations from an expert U.S. panel, facilitated by the American Foregut Society, for adults with objectively confirmed GERD. The panel concluded that optimization of medical therapy with continued PPI and tapering to the lowest effective dose is appropriate for complete responders without a significant hernia. For PPI non-responders, invasive

therapy should be pursued only when objective evidence of abnormal reflux is present (e.g., positive impedance-pH on PPI), recommending:

- Laparoscopic fundoplication (LF) and magnetic sphincter augmentation (MSA) are appropriate options for complete or partial PPI responders regardless of whether a clinically significant hiatal hernia is present.
- Transoral incisionless fundoplication (TIF) is considered appropriate for complete or partial responders without a clinically significant hiatal hernia.
- Radiofrequency energy delivery is not appropriate for complete or partial responders.

National Institute for Health and Care Excellence (NICE) issued the following interventional practice guidelines (IPG) for the treatment of GERD:

- In 2023 (IPG753), NICE concluded that the evidence on the safety of endoluminal gastroplication for gastroesophageal reflux disease is adequate; however, evidence on its efficacy is inadequate in quality, particularly in terms of patient selection and long-term outcomes. Therefore, this procedure should be used only in research.
- In 2013 (IPG461), NICE concluded that the evidence on the safety of endoscopic radiofrequency ablation for gastro-esophageal reflux disease is adequate in the short and medium term, but there is uncertainty about longer-term outcomes. There is evidence of symptomatic relief, but objective evidence on reduction of reflux is inconclusive.

REGULATORY STATUS

The U.S. Food and Drug Administration (FDA) regulates devices for transendoscopic procedures as medical devices. All devices require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed 2026 Jan 27]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most serious type of recalls. Available from: https://www.fda.gov/medical-devices/medical-device-safety/medical-device-recalls-and-early-alerts [accessed 2026 Jan 27]

Radiofrequency Thermal Energy

In 2000, the Stretta System was cleared for marketing by the FDA through the 510(k) process for general use in the electrosurgical coagulation of tissue and was specifically intended for use in the treatment of GERD. In 2010, Mederi Therapeutics began manufacturing the Stretta device. Mederi was acquired by Respiratory Technology Corporation in 2018.

Endoluminal Endoscopic GEJ-Reshaping

The Medigus Ultrasonic Surgical Endostapler (MUSE), formerly the SRS Endoscopic Stapling System, was cleared for marketing by the FDA through the 510(k) process in 2012 (K120299) and 2014 (K132151). MUSE is intended for endoscopic placement of surgical staples in the soft tissue of the

esophagus and stomach to create anterior partial fundoplication for the treatment of symptomatic chronic GERD in patients who require and respond to pharmacologic therapy.

The EsophyX (EndoGastric Solutions) is a transesophageal (or transoral) incisionless fundoplication (TIF) device that was originally cleared for marketing by the FDA through the 510(k) process in 2007 and has subsequently undergone 2 evolutions: Generation 2=EsophyX2 iterations (E2-Plus, HD) and Generation 3=Z iterations (EZ/ZR, Z+). In 2007, EsophyX (EndoGastric Solutions) was cleared for marketing by the FDA through the 510(k) process for full-thickness plication. In 2016, EsophyX Z Device with SerosaFuse Fasteners was cleared for marketing by the FDA through the 510(k) process (K160960) for use in transoral tissue approximation, full-thickness plication, ligation in the gastrointestinal tract, narrowing the gastroesophageal junction, and reduction of hiatal hernias of 2 cm or less in patients with symptomatic chronic GERD. In June 2017, EsophyX2 HD and the third-generation EsophyX Z Devices with SerosaFuse fasteners and accessories were cleared for marketing by the FDA through the 510(k) process (K171307) for expanded indications, including patients who require and respond to pharmacologic therapy and patients with hiatal hernias larger than 2 cm when a laparoscopic hiatal hernia repair reduces a hernia to 2 cm or less. An additional FDA 510(k) clearance (K172811) occurred in October 2017 for new product specification iterations of EsophyX2 HD and EsophyX Z Devices. This clearance allows for "a moderate increase in the upper limit of the temporary Tissue Mold clamping pressure occurring during each fastener deployment." A 2024 FDA 510(k) clearance (K240879) updated instructions for use and other device labeling.

The GERDx-System was cleared through the 510(k) process in 2024 (K233240) for endoscopic full-thickness plication in individuals with chronic GERD who require and respond to pharmacological therapy. The device was found substantially equivalent to the NDO Surgical Endoscopic Plication System (K071553), which was cleared in 2007 for the treatment of chronic GERD but was later removed from the market due to durability concerns and limited long-term clinical effectiveness. The GERDx-System incorporates technological refinements intended to improve safety and performance compared with its predicate device.

The Bard EndoCinch Suturing System received FDA 510(k) clearance on January 5, 2001 (K003956), and the NDO Surgical Endoscopic Plication System (Plicator) received FDA 510(k) clearance on April 17, 2003 (K023234) for the treatment of chronic GERD. Although both devices were cleared for marketing for the treatment of GERD, they are no longer available for clinical use in the United States. They were discontinued or withdrawn from the market due to limited efficacy, durability concerns, and lack of sustained commercial adoption.

Esophageal Bulking Agents

Durasphere and plexiglas (PMMA) do not currently have FDA approval for use in an anti-reflux application. The Gatekeeper System was withdrawn in late 2005, before FDA approval. Enteryx received FDA clearance 2003 and was recalled from market October 2005 based on a joint decision by the FDA and Boston Scientific. The recall was initiated by Boston Scientific, based upon growing data evidence of serious adverse effects.

DISCLAIMER

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgement when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

DESCRIPTION

Care provided by a non-participating provider to a new enrollee of the Plan to ensure continuity of care and a smooth transition to a participating provider.

POSITION STATEMENT

CDPHP allows a new enrollee to continue an ongoing course of treatment with their current, non-participating health care provider during a transitional period of up to 60 days from the effective date of enrollment, when they are receiving services for **ONE** the following conditions:

- A life-threatening disease or condition defined as one that, according to the current diagnosis of the attending physician, has a high probability of death.
- A degenerative and disabling condition defined as any medically determinable physical or mental condition or disease which, according to the current diagnosis of the enrollee's attending physician requires specialized medical care over a prolonged period of time
- A new enrollee who is in the second or third trimester of pregnancy at the effective date of enrollment, in which case the transitional period includes the provision of post-partum services directly related to the delivery.

In addition, the provider must agree to all of the following:

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: TRANSITIONAL CARE – NEW ENROLLEE

- Accept the CDPHP reimbursement rates.
- Adhere to the CDPHP quality management requirements.
- Provide CDPHP with necessary medical information related to care rendered.
- Adhere to all the CDPHP policies and procedures in rendering care to the enrollee, including but not limited to the referral process, obtaining pre-authorizations when indicated, and providing a treatment plan for review and approval.
- Only render care for those services provided for in the enrollee's contract.
- Provider must sign a statement/letter indicating agreement to the above terms and conditions.

POLICY CONSIDERATIONS

Enrollees requiring transitional care will be assigned a case manager to assist both enrollee and provider with referral and authorization of services, and to ensure a smooth transfer of care to a participating provider.

CDPHP PRODUCT VARIATIONS

CHILD HEALTH PLUS	Subject to all terms and conditions noted above in the policy. • Child Health Plus defines postpartum period as a 12-month timeframe.
MEDICARE ADVANTAGE	New enrollees must transition all care to Medicare Advantage network providers upon effective date.
SELECT PLAN/HARP	Subject to all terms and conditions noted above in the policy. • Medicaid defines postpartum period as a 12-month timeframe. In the absence of a written agreement to the Plan's fee schedule, CDPHP will reimburse non-participating providers at the Medicaid fee-for-service rates to ensure continuity of care.

POLICY HISTORY

This section is intended to provide only highlights of the policy changes. The policy should always be reviewed in its entirety to ensure a comprehensive understanding of coverage.

Effective Date	Update
6/14/2023 *No change to effective date of policy	Under the Position Statement clarified that only one of the bullets needs to be met.
6/14/2023 *No change to effective date of policy	No changes to criteria. Clarified a degenerative and disabling condition.
6/14/2023	Under the CHP section, added new DOH update that extends the postpartum timeframe to 12 months.
3/1/2023	Under the Position Statement, clarified inclusion of a new enrollee in either their second or third trimester. Under the Medicaid section, added new DOH update that extends the postpartum timeframe to 12 months.
8/1/21	Removed statement regarding pre-existing conditions in the Policy Considerations section.

POLICY NAME: TRANSITIONAL CARE – PROVIDER LEAVES THE NETWORK

POLICY EFFECTIVE DATE:	6/14/2023
Policy Control #:	1370/20.000195
Next Annual Review:	July, 2027

DISCLAIMER

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgement when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

DESCRIPTION

Care rendered by an enrollee's health care practitioner who leaves the CDPHP participating network, for reasons other than imminent harm to patient care, a determination of fraud or a final disciplinary action by a state licensing board or other governmental agency that impairs the health care practitioner's ability to practice, to ensure continuity of care and a smooth transition to a participating practitioner.

POSITION STATEMENT

CDPHP allows an enrollee to continue an ongoing course of treatment with their current health care provider for a transitional period of up to 90 days, from either the date of notice or the effective date of termination, whichever is later **or**

If the enrollee is pregnant and undergoing a course of treatment for the pregnancy on the date the provider's contractual obligation to provide services to CDPHP enrollees terminates. In which case, the transitional period (which could extend longer than 90 days) includes the delivery and post-partum care directly related to the delivery.

In addition, the provider must:

- Accept the CDPHP reimbursement rates.
- Adhere to the CDPHP quality management requirements.

POLICY NAME: TRANSITIONAL CARE – PROVIDER LEAVES THE NETWORK

- Provide CDPHP with necessary medical information related to care rendered.
- Adhere to all the CDPHP policies/procedures in rendering care to the enrollee including but not limited to the referral process, obtaining pre-authorizations when indicated and providing a treatment plan for review and approval.
- Only render care for those services provided for in the enrollee's contract.

POLICY CONSIDERATIONS

Enrollees requiring transitional care will be offered the services of a case manager to assist with a smooth transfer of care to a new participating practitioner.

CDPHP PRODUCT VARIATIONS

CHILD HEALTH PLUS	Subject to all terms and conditions noted above in the policy. • Child Health Plus defines postpartum period as a 12-month timeframe.
MEDICARE ADVANTAGE	Subject to all terms and conditions noted above in the policy. • Enrollees must transition all care to another Medicare Advantage network provider.
SELECT PLAN/HARP	Subject to all terms and conditions noted above in the policy. • Medicaid defines postpartum period as a 12-month timeframe. • In the absence of a written agreement to the Plan's fee schedule, CDPHP will reimburse non-participating providers at the Medicaid fee-for service rates to ensure continuity of care.

Policy/Procedure Name: Tregzi (allogeneic regulatory T cell immunotherapy with HSPC and T cells-vldq) **Control Number: 1350/20.000597**

Disclaimer Notice

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Healthcare practitioners shall exercise their own medical judgment when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

Background

Tregzi (allogeneic regulatory T-cell immunotherapy with HSPC and T-cells-vldq) is an allogeneic regulatory T-cell based immunotherapy containing hematopoietic stem and progenitor cells (HSPCs) and T-cells indicated for the treatment of hematological malignancies while improving chronic graft-versus-host disease (cGVHD)-free survival in matched donor hematopoietic stem cell transplantation with myeloablative preparative regimen.[1] Administration of Tregzi involves four separate infusion bags for intravenous infusion: HSPCs, regulatory T-cells (Tregs), conventional T-cells (Tcons), and Tcon diluent. Its recommended dose is a single intravenous infusion of ≥ 1.0 × 106 HSPCs per kg, 1.3×10^6 to 3.5×10^6 Tregs per kg, and 1.3×10^6 to 3.5×10^6 Tcons per kg.

Chronic graft-versus-host disease is a major complication of allogeneic hematopoietic stem cell transplant (HSCT) that affects approximately 30% to 70% of HSCT recipients.[2] The condition is characterized by an immune-mediated response that leads to chronic inflammation and fibrosis of multiple organs.[2,3] Management of cGVHD involves treatment with immunosuppressants such as steroids and calcineurin inhibitors.

Approval of Tregzi was supported by the PRECISION-T Phase III Trial where 187 subjects between the ages of 18 and 65 years were enrolled and randomized to receive either Tregzi with single agent tacrolimus or a control arm comprised of a peripheral blood stem cell allograft with tacrolimus and methotrexate (Tac/MTX).[4,5] Subjects were diagnosed with either acute leukemia or myelodysplastic syndrome and received myeloablative conditioning. The primary endpoint evaluated survival free from moderate-to-severe cGVHD (cGFS). Patients treated with Tregzi at the one-year follow-up demonstrated 78% cGFS compared to 38.4% in the convention stem cell transplant plus Tac/MTX arm. Additional efficacy endpoints highlighted a 63.1% cGVHD and relapse-free survival at one year compared to 30.9%, respectively.

Warnings and precautions include a risk of graft failure, GVHD, infusion reactions, secondary malignancies and malignancies of donor origins, and transmission of infectious agents.[1] For further reduction in risk of developing GVHD, it is recommended that patients are treated with a single agent calcineurin inhibitor as prophylaxis. Adverse reactions were generally consistent with conventional hematopoietic stem cell transplants – some of the most common adverse reactions with incidence ≥ 20% were infections, gastrointestinal disorders (diarrhea, abdominal pain, vomiting, nausea), mucositis, and rash.[1,4]

Summary

Effective Date of Policy:	9/25/2026
Indications	Use in matched donor hematopoietic stem cell transplantation with myeloablative preparative regimen, for hematopoietic and immunologic reconstitution and to improve chronic graft-versus-host disease (cGVHD)-free survival, in the treatment of adults with hematological malignancies
HCPCS	J3590 (NOC)

Required Criteria for Approval - Medical

1. Must be prescribed by a hematologist, oncologist, or physician experienced in the treatment of hematologic malignancies **AND**
2. The patient must be eligible for an allogeneic hematopoietic (stem) cell transplant (HSCT) **AND**
3. The patient must receive therapy at an authorized treatment center **AND**
4. Must be at least 18 years of age **AND**
5. Must be diagnosed with one of the following:
    a. Acute myeloid, lymphoid, or mixed phenotype/undifferentiated leukemia in complete remission (CR) or in complete remission with incomplete hematologic recovery (CRi); See appendix for definitions of CR and CRi
    b. Myelodysplastic syndromes (MDS) with ≤ 10% blast burden in the bone marrow; **AND**
6. Consideration may be given to other hematological malignancies for which myeloablative allogeneic HSCT is an established treatment per NCCN guidelines
7. Provider must attest the patient will be treated with at least a single agent calcineurin inhibitor (such as tacrolimus) as prophylaxis to decrease the risk of graft versus host disease (GHVD) **AND**

8. Must have been screened and found seronegative for HIV-1 or -2 antibody, HTLV-1 or -2 antibody, Hepatitis B sAg, and Hepatitis C antibody **AND**
9. Must have a matched related or unrelated donor who is an 8/8 match for HLA-A, -B, -C, and DRB1 **AND**
10. Tregzi will not be authorized if the patient meets any of the following:
    a. Patient had a prior allogeneic hematopoietic stem cell transplant
    b. Hematopoietic cell transplantation-specific Comorbidity Index (HCT-CI) > 4
    c. Any uncontrolled autoimmune disease requiring active immunosuppressive treatment
    d. Current uncontrolled bacterial, viral, or fungal infection
11. Tregzi is indicated for one-time intravenous administration only and therefore will not be authorized for retreatment. Retreatment will be considered experimental/investigational when any FDA approved gene or cellular therapy, or any other gene or cellular therapy under investigation, has been previously administered
12. Tregzi is considered investigational for all other non-FDA approved indications
13. Approval will be for 6 months to allow one-time administration

Appendix

Definitions of Complete Remission (CR) and Complete Remission with Incomplete Hematologic Recovery (CRi)[6]

Definition of CR for AML and MPAL (meets all criteria, 1-5)

1. Bone marrow blasts < 5% by morphologic examination
2. ANC > 1.0×10^9/L (1,000/µL)
3. Absence of circulating blasts in the peripheral blood by morphologic examination
4. No evidence extramedullary disease
5. Platelet count > 100×10^9/L (100,000/µL)

CRi is defined as meeting all CR criteria except for residual neutropenia (< 1.0×10^9/L) and/or thrombocytopenia (< 100×10^9/L).

Definition of CR for ALL (meets all criteria, 1-6)

1. < 5% blasts in the bone marrow
2. Normal maturation of all cellular components in the bone marrow
3. No extramedullary disease (e.g., central nervous system, soft tissue disease)
4. ANC > 1,000/µL
5. Platelet count >100,000/µL
6. Transfusion independence

CRi is defined as meeting all CR criteria except for residual neutropenia (≤ 1.0×10^9/L) and/or thrombocytopenia (≤ 100×10^9/L).

Policy Guidelines

1. Utilization Management are contract dependent. Refer to specific contract/benefit language for exclusions.
    a. Coverage criteria may be dependent on the contract renewal date.
    b. Coverage of drugs listed in this policy are contract dependent.
    c. Not all contracts/benefits allow coverage of healthcare professional administered drugs as part of their pharmacy benefit
    d. Not all contracts/benefits cover all medical infusible drugs.
2. Clinical documentation must be submitted for each request (initial and recertification [if applicable]) unless otherwise specified (e.g., provider attestation required). Supporting documentation includes, but is not limited to, progress notes documenting previous treatments and treatment history, diagnostic testing, laboratory test results, genetic testing or biomarker results, imaging and other objective or subjective measures of benefit. Requested dosing must remain consistent with FDA-approved dosing recommendations.
3. This policy does not apply to Medicare Part D and D-SNP pharmacy benefits. The drugs in this policy may apply to all other lines of business including Medicare Advantage.
4. Unless otherwise indicated within drug specific criteria, the drugs listed in this policy are administered by a healthcare professional and therefore are covered under the medical benefit.

5. All utilization management requirements outlined in this policy are compliant with applicable New York State insurance laws and regulations. Policies will be reviewed and updated as necessary to ensure ongoing compliance with all state and federally mandated coverage requirements.
6. For commercial contracts, medical necessity determinations align with the Certificate of Coverage issued by the Health Plan, which states that covered services must be clinically appropriate and not primarily for the convenience of the member, the member's family, or the provider.
7. This policy is based on available evidence as of the last review date. Coverage determinations are subject to applicable plan documents, state and federal regulations, and individual patient circumstances. This policy does not constitute medical advice.
8. This policy is subject to ongoing revision. Newly marketed drugs and existing drugs with new indications may be subject to prior authorization until formal coverage criteria are established. Inclusion of a drug in this policy does not guarantee its current availability on the market, as some agents may be discontinued, withdrawn, or otherwise unavailable. As product status changes, drugs may be removed from the policy.
9. For members with Medicare Advantage, medications with a National Coverage Determination (NCD) and/or Local Coverage Determination (LCD) will be covered pursuant to the criteria outlined by the NCD and/or LCD. NCDs/LCDs for applicable medications can be found on the CMS website at https://www.cms.gov/medicare-coverage-database/search.aspx. In the absence of a Medicare National Coverage Determination (NCD), Local Coverage Determination (LCD), or other Medicare coverage guidance, CMS permits a Medicare Advantage Organization (MAO) to establish its own coverage determinations in accordance with 42 CFR § 422.101(b)(6). Indications that have not been addressed by the applicable medication's LCD/NCD will be covered in accordance with criteria determined by the Health Plan. Step therapy requirements may be imposed in addition to LCD/NCD requirements.
10. Manufacturers may either discontinue participation in, or may not participate in, the Medicaid Drug Rebate Program (MDRP). Under New York State Medicaid requirements, physician-administered drugs must be produced by manufacturers that participate in the MDRP. Products made by manufacturers that do not participate in the MDRP will not be covered under Medicaid Managed Care/HARP lines of business. Drug coverage will not be available for any product from a non-participating manufacturer. For a complete list of New/Reinstated & Terminated Labelers please visit: https://www.medicaid.gov/medicaid/prescriptiondrugs/medicaid-drug-rebate-program/newreinstated-terminated-labeler-information/index.html
11. The requested site of care may impact approval timeframe and is subject to review.
12. The following applies to all gene and cellular therapies unless otherwise specified within the drug-specific coverage criteria:
    a. Administration, Retreatment, and Treatment with Additional or Other Gene/Cellular Therapies
        i. One-Time Administration
            1. Most gene and cellular therapies, whether autologous, allogeneic ("off-the-shelf"), or in vivo gene-transfer therapies, are designed and studied as one-time treatments.
            2. Repeat dosing, reinfusion, or sequential therapy with other gene or cellular products has not been established as safe, effective, or clinically appropriate.
        ii. Retreatment/Repeat Administration
            1. Retreatment with the same gene or cellular therapy product is considered experimental and investigational because:
                a. Clinical trials evaluated these therapies as single-administration interventions
                b. Safety, efficacy, and durability of a second administration have not been established
                c. Risks of immune activation, insertional mutagenesis, or vector immunity may be increased with repeat dosing
        iii. Treatment with an Additional or Other Gene/Cellular Therapy
            1. Treatment with an additional or different gene or cellular therapy after prior exposure to any gene or cellular therapy is also considered experimental and investigational, unless supported by evidence demonstrating (a-c):
                a. Anticipated clinical benefit beyond available standard therapies
                b. Safety of sequential administration
                c. Justification for selecting a second gene/cellular intervention after a prior one
            2. This includes, but is not limited to:
                a. Switching between CAR-T products (e.g., CD19 → CD19 or CD19 → BCMA)
                b. Switching between autologous and allogeneic cellular therapies
                c. Sequential use of CAR-T, TCR-T, NK-cell therapies, or other genetically engineered cell therapies
                d. Receiving a gene therapy after previous gene or cellular therapy exposure

e. Receiving an in vivo gene therapy following any prior vector-based therapy

iv. Prior Gene/Cell Therapy Exposure

1. An individual is generally not eligible for additional gene or cellular therapy if they have previously received:
   a. Any autologous cellular therapy (e.g., CAR-T, TCR-T, TIL)
   b. Any allogeneic genetically modified cellular therapy
   c. Any in vivo gene therapy (e.g., AAV, lentiviral vector)
   d. Any ex vivo gene-modified cell product
   e. Are being considered for any other gene or cellular therapy without documented evidence supporting safety and anticipated benefit

MEDICAL POLICY

Medical Policy Title	**Tumor-Treatment Fields Therapy**
Policy Number	**6.01.45**
Current Effective Date	**November 1, 2026**
Next Review Date	**April 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Alternating electrical field therapy (tumor-treatment field (TTF) therapy) using Optune (Novocure, Portsmouth, New Hampshire) for treatment of recurrent supratentorial glioblastoma multiforme (GBM) is considered **medically appropriate**, when **ALL** the following criteria have been met:

   A. The patient has had a first or second recurrence of GBM;

   B. The patient has a Karnofsky Performance Status (KPS) of 60 or greater;

   C. The patient has not received prior treatment with Bevacizumab;

   D. The device is to be used as monotherapy after failure of standard medical therapy (e.g., chemotherapy, surgery, and/or radiation therapy);

   E. The patient is 22 years or older; **and**

   F. Documentation includes the following:

      1. The patient has histologically confirmed GBM (documentation of pathology required);

      2. The Optune (Novocure) will be initially allowed for up to six (6) months if the patient is compliant (18 hours or more per day) with the regimen;

      3. Continued use after six (6) months will require:

         a. Documentation that the patient has been compliant (18 hours or more per day); **and**

         b. Documentation that there has been no progression of tumor.

II. TTF therapy using Optune for treatment of newly diagnosed supratentorial GBM is considered **medically appropriate** when **ALL** the following criteria have been met:

   A. The device is to be used as an adjunct with the chemotherapy drug temozolomide (TMZ);

   B. The therapy follows standard treatments that include maximal debulking surgery and completion of radiation therapy, together with concomitant standard of care chemotherapy;

   C. The patient is 22 years or older; **and**

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

D. Documentation includes the following:
    1. The patient has histologically confirmed GBM (documentation of pathology required);
    2. The Optune (Novocure) will be initially allowed for up to six (6) months if the patient is compliant (18 hours or more per day) with the regimen;
    3. Continued use after six (6) months will require:
        a. Documentation that the patient has been compliant (18 hours or more per day); **and**
        b. Documentation that there has been no progression of tumor.

III. TTF therapy is considered **investigational** for all other indications, including but not limited to:
    A. Mesothelioma;
    B. Metastatic non-small cell lung cancer (mNSCLC);
    C. Unresectable locally advanced pancreatic adenocarcinoma.

Device Repair

IV. Repair of a medically necessary Optune device or components not under warranty will be considered **medically appropriate** when the following criteria are met:
    A. Physician documentation includes **ALL** the following:
        1. date of device implantation/initiation;
        2. manufacturer warranty information, if applicable;
        3. attestation that the patient has been compliant with the use of device and will continue to benefit from the use of device;
    B. The device is no longer functioning adequately; and **BOTH** of the following criteria are met:
        1. inadequate function interferes with activities of daily living; **and**
        2. repair is expected to make the equipment fully functional (as defined by manufacturer).

V. Repair of equipment damaged due to patient neglect, theft, abuse, or when another available coverage source is an option (e.g., homeowners, rental, auto, liability insurance, etc.) is **ineligible for coverage**.

Device Replacement

VI. Replacement of a medically necessary Optune device or components not under warranty will be considered **medically appropriate** when **EITHER** of the following criteria are met:
    A. The device is no longer functioning adequately and has been determined to be non-repairable or the cost of the repair is in excess of the replacement cost; **or**
    B. There is documentation that a change in the patient's condition makes the present unit non-functional and improvement is expected with a replacement unit.

VII. The replacement of a properly functioning Optune device and its components or accessories is considered **not medically necessary**. This includes, but is not limited to, replacement desired due to advanced technology or in order to make the device more aesthetically pleasing;

VIII. The replacement of equipment damaged or lost due to patient neglect, theft, abuse, or when another available coverage source is an option (e.g., homeowners, rental, auto, liability insurance, etc.) is **ineligible for coverage**.

IX. Accessories or components for an Optune device that are considered not medically necessary or investigational by peer-reviewed literature will also be considered as **not medically necessary or investigational** by the Health Plan.

DESCRIPTION

Glioblastoma multiforme (GBM), is the most common and aggressive primary intracranial tumor, with approximately 33% of patients surviving one year and less than 5% surviving more than five (5) years. Median survival with optimal therapy has been reported to be 10-to-15 months, with most tumors recurring within seven-to-nine months, despite multimodal treatment (e.g., repeat surgery, re-irradiation, and chemotherapy). Choice of chemotherapy for treatment in the case of recurrence varies, but may include alkylating agents (e.g., lomustine, carmustine, procarbazine), re-treatment with temozolomide, and, more recently, bevacizumab either alone or in combination with other agents. Overall survival after recurrence is relatively short, even with optimal therapy. New or novel treatments, such as TTF therapy, are being investigated to improve survival in patients with GBM.

TTF therapy is delivered via the Optune, which is a battery-powered, portable device that generates alternating low-intensity, intermediate electrical fields (100-300 kHz) by four (4) disposable electrode arrays (replaced one (1) to two (2) times per week) that are non-invasively attached to the patient's shaved scalp, placed in such a way as to encompass the tumor. The alternating low intensity electrical field is thought to disrupt cell division of the cancer cells, so that either cell division does not occur, or it is ineffective, resulting in death of the cancer cells without harming the normal healthy cells. The device is used by the patient at home on a continuous basis (18 hours per day) for the duration of treatment, which can last for several months. Patients can carry the device in a backpack or shoulder pack while conducting activities of daily living.

SUPPORTIVE LITERATURE

The United States Food and Drug Administration (FDA) approval of the Optune NovoTTF-100A

system, was based on a phase three (3), multi-national, prospective, randomized, controlled trial (RCT) (Stupp et al., 2012). Participating in the study were 237 patients with relapsed or progressive GBM, despite conventional radiotherapy, who were randomized in a 1:1 ratio to receive TTF therapy (delivered by the NovoTTF-100A System) only (n=120) or the best standard of care chemotherapy (active control) (n=117). Patient characteristics were balanced in both groups, with median age of 54 years and median Karnofsky Performance Status (KPS) score of 80%. More than 80% of participants had failed two or more prior chemotherapy regimens, and 20% had failed bevacizumab prior to study enrollment. Ninety-seven percent (116) of the 120 participants in the TTF group started treatment, and 93 participants (78%) completed one (1) cycle (four weeks) of therapy. Discontinuation of TTF therapy occurred in 27 participants (22%), due to noncompliance or the inability to manage the device. For each TTF treatment month, the median compliance was 86% (range, 41%-98%), which equaled a mean use of 20.6 hours per day. In the active control group, 113 (97%) of the 117 assigned participants received chemotherapy, and all but one individual completed a full treatment course. Twenty-one participants (18%) in the active control group did not return to the treatment site, and details on disease progression and toxicity were not available. This RCT did not reach its primary end point of improved survival compared with active chemotherapy. With a median follow-up of 39 months, 220 participants (93%) had died. Median survival was 6.6 months in the TTF group, compared with 6.0 months in the active control group (hazard ratio, 0.86; 95% confidence interval [CI], 0.66 to 1.12; p=0.27). For both groups, one-year survival was 20%. The survival rates for two- and three-year survival were 8% and 4%, respectively, for the TTF group versus 5% and 1%, respectively, for the active control group. Progression Free Survival (PFS) rate at six months was 21.4% in the TTF group, compared with 15.1% in the active control group (p=0.13). Limitations of the trial included a somewhat heterogeneous patient population, with participants included after progression of one or several lines of chemotherapy, as well as the use of different chemotherapy regimens in the control group. Another limitation was the absence of a placebo/supportive care arm. In the setting of advanced disease, the supportive care arm would have been useful to gauge the safety and efficacy of treatment for both groups of patients. Treatments used in the active control arm (best standard of care chemotherapy) in the recurrent disease setting have previously demonstrated limited efficacy, thus limiting the ability to determine the true treatment effect of TTF. Data from a trial of TTF versus placebo, or TTF plus standard chemotherapy, versus standard chemotherapy alone, would, therefore, provide a better assessment of treatment efficacy.

A subgroup analysis of patient data of this phase 3 trial (Wong et al 2014) evaluated the different characteristics of responders and non-responders in the TTF group, compared to the active control group. More patients in the TTF arm were considered responders (14 of 120, versus seven (7) of 117 in the chemotherapy arm). Median response time was longer for those in the TTF arm than the chemotherapy arm (7.3 months versus 5.6 months, p<0.001), and there was a strong correlation (Pearson's r) between response and overall survival in the TTF arm (p<0.001), but not in the chemotherapy arm (p=0.29). Compared with the chemotherapy arm, a higher proportion of responders in the TTF arm had a prior low-grade histology (36% vs 0%). These differences in treatment responder groups suggest that TTF therapy may differentially benefit certain types of GBM; however, the small numbers of responders in both groups limits generalizations that can be drawn from this analysis.

An analysis of the NovoTTF-100A Patient Registry Dataset (PRiDe) of 457 patients with recurrent GBM who were treated with NovoTTF therapy in the United States between October 2011 and November 2013, and a comparison to patient data in the Phase 3 trial, were performed (Mrugula et al 2014) to provide a larger data set of patients with recurrent GBM treated with TTF therapy. No new adverse events in the PRiDe group of patients were reported, compared to the Phase 3 trial group. However, median overall survival was longer in the TTF group in the PriDe group (9.6 months), compared to the TTF group in the Phase 3 trial (6.6 months) or to the active chemotherapy group in the Phase 3 trial (6.0 months). Median treatment time was almost double for the TTF PriDe group, compared to either the TTF or chemotherapy group in the Phase 3 trial. Favorable prognostic factors in the PriDe group included 75% or more daily compliance with the device, treatment with TTF at first recurrence, no prior treatment with bevacizumab, and Karnofsky Performance Score (KPS) 90 or greater. The authors suggested that there are subsets of patients who derive significant benefit from TTF therapy and that TTF therapy using the NovoTTF-100A device is safe and efficacious to treat recurrent GBM.

The FDA approval of the Optune device (formerly called the NovoTTF-100A system) for newly diagnosed GBM was based on the results from a clinical trial involving 695 patients who were newly diagnosed with GBM. The study compared those who used the device with temozolomide (TMZ) to those receiving TMZ alone (Stupp, 2015). Patients who used the device along with TMZ lived, on average, about seven (7) months with no disease progression, compared to four (4) months for those who had the drug alone. The device plus TMZ group survived for an average of 19.4 months after starting treatment, compared to 16.6 months for those who were treated with TMZ alone.

In 2019, through the humanitarian device exemption (HDE) process, the FDA approved the Optune Lua system (formerly called the NovoTTF-100L) for treatment of adult patients with unresectable, locally advanced or malignant pleural mesothelioma (MPM), to be used concurrently with pemetrexed and platinum-based chemotherapy (the current gold-standard of treatment). The decision was based on the results of the industry-designed and sponsored STELLAR trial (NCT02397928), which was summarized by Ceresoli et al. This was a prospective, single-arm, multi-center study of 80 participants treated between 2015 and 2018, who had inoperable, previously untreated MPM. The primary endpoint of the trial was overall survival, which was measured from time of diagnosis until date of death. Fifty patients (63%) were treated with a carboplatin and pemetrexed combination with TTF, and 30 patients (37%) received cisplatin and pemetrexed with TTF. Median overall survival was 18.2 months (95% CI 12.1-25.8) and comparable to other recent study results for median overall survival of chemotherapies for treatment of MPM. Even though the median overall survival, objective responses, and progression-free survival results did not appear to be impacted with TTF therapy, the similar outcomes reported in this study were achieved without an increase in systemic toxicity. Thirty-two patients did have severe adverse events during the trial period, which is also consistent with other trials of pemetrexed (anemia, neutropenia, and skin reaction being the most common). The majority of patients did have mild medical device reactions at the site of array adherence on the skin. This study's small sample size, lack of a control group, and lack of quality-of-life assessment did not provide enough information to draw conclusions on the efficacy of this therapy versus standard medical treatment. Further randomized clinical trials are needed.

Leal et al (2023) reported on a pivotal phase 3, open-label, randomized study (LUNAR). The study aimed to compare the addition of TTF therapy to standard systemic therapy with standard systemic therapy alone in patients with metastatic non-small-cell lung cancer. Between February 2017 and November 2021, 276 patients were enrolled and randomly assigned to receive TTFields therapy with standard therapy (n=137) or standard therapy alone (n=139). Their median age was 64 years, 178 (64%) were male and 98 (36%) were female, and 232 (84%) were current or former smokers. At baseline, the majority (156 [57%]) had non-squamous histology, 43 (16%) had liver metastasis, and ten (4%) had an ECOG performance score of 2. TTFields therapy (150 kHz) was delivered continuously to the thoracic region with the recommendation to achieve an average usage of at least 75% of each day (18 h/day) with the NovoTTF device system (device manufactured by Novocure). The primary endpoint was overall survival in patients receiving TTFields therapy with standard therapy compared with standard therapy alone. Key secondary endpoints were overall survival in subgroups receiving either docetaxel or an immune checkpoint inhibitor. Other secondary endpoints (reported here) were progression-free survival and overall response rate (both per radiological assessment); overall survival by squamous and non-squamous histology; measurement of patient-reported, health-related quality-of-life scores; and adverse events. Secondary endpoints of overall survival and progression-free survival in TTFields therapy-treated subgroups with average monthly device usage of more than 75% and 75% or less; progression free survival by squamous and non-squamous histology; overall survival and progression-free survival in subgroups who received nivolumab, pembrolizumab, or atezolizumab; and overall survival of patients who received TTFields therapy with docetaxel compared with patients treated with an immune checkpoint inhibitor alone will be reported elsewhere as part of more extensive analyses. Over the entire course of the study, a monthly average device usage of at least 18 h/day (75% of each day) was reached by 13 (19%) of 67 patients in the immune checkpoint inhibitor subgroup and 17 (26%) of 66 patients in the docetaxel subgroup. Overall survival was significantly longer with TTFields therapy and standard therapy versus standard therapy alone. Median overall survival was 13.2 months with TTFields therapy and standard therapy compared with 9.9 months with standard therapy alone, yielding an HR of 0.74 in favor of TTFields therapy. The one-year overall survival rate was 53% with TTFields therapy and standard therapy, and 42% with standard therapy alone. The overall response rate with TTFields therapy and standard therapy was 20.4% versus 17.3% with standard therapy alone. All complete responses (n=5) occurred in patients receiving an immune checkpoint inhibitor (four with TTFields therapy, one with immune checkpoint inhibitor alone). Study limitations include the open-label design and study being industry sponsored. Other limitations are that the study enrolled a low number of patients with brain metastases, potentially affecting the generalizability of these findings to that population. LUNAR was also initiated before the advent of standard genetic profiling by next-generation sequencing in non-small cell lung cancer, and thus little information about the relationship between TTFields therapy efficacy and tumor genetic subtype is available. Authors concluded that data from this study suggests that TTFields therapy is efficacious in metastatic non-small-cell lung cancer and should be considered as a treatment option to manage the disease. Additional studies are warranted to validate the benefit of TTFields therapy with standard systemic therapies in non-small-cell lung cancer.

In the pivotal phase III Panova-3 study, Babiker et al (2025) sought to confirm the safety and

efficacy of TTFields in patients with unresectable locally advanced pancreatic adencocarcinoma (LA-PAC). 571 patients with newly diagnosed LA-PAC were randomly assigned to receive gemcitabine and nab-paclitaxel by intravenous infusion once a day on days 1, 8, and 15 of a 28-day cycle with or without TTFields. The primary end point was overall survival (OS). Secondary end points included progression-free survival (PFS), local PFS, pain-free survival, and overall response rate (ORR). OS was significantly prolonged using TTFields with gemcitabine/nab-paclitaxel versus gemcitabine/nab-paclitaxel (median, 16.2 months versus 14.2 months. PFS, local PFS, and ORR were not improved. Pain-free survival was significantly prolonged with TTFields with gemcitabine/nab-paclitaxel (median, 15.2 months versus 9.1 months. Authors concluded that this study demonstrated significant OS, pain-free survival, and distant PFS benefits for TTFields with gemcitabine/nab-paclitaxel versus gemcitabine/ nab-paclitaxel. The study had several limitations including, but not limited to, industry sponsorship, small gain in OS, high dependence on treatment adherence and device burden, no improvement in PFS or ORR, open label study design and lack of independent confirmatory trials.

PROFESSIONAL GUIDELINE(S)

The National Comprehensive Cancer Network (NCCN) Clinical Practice Guidelines for Central Nervous System Cancers V.3.2025 states that due to lack of clear efficacy data, the panel is divided regarding recommending alternating electric field therapy for the treatment and re-irradiation of recurrent glioblastoma. Concurrent treatment with adjuvant TMZ and alternating electric fields is a category 1 recommendation for newly diagnosed glioblastoma patients ≤ 70 years of age who have a good PS. This is also considered a reasonable treatment option for patients > 70 years of age with good PS and newly diagnosed glioblastoma who are treated with standard focal brain radiation and concurrent daily TMZ.

The NCCN Clinical Practice Guidelines for Malignant Pleural Mesothelioma V.2.2026 do not reference TTF therapy as a treatment for this indication.

The NCCN Clinical Practice Guidelines for Non-Small Cell Lung Cancer V.3.2026 do not refer to TTF therapy as a treatment for this indication.

In addition to malignant pleural mesothelioma, TTF is being investigated in non-small cell lung cancer, brain metastases from non-small cell lung cancer, pancreatic cancer, ovarian cancer, hepatocellular carcinoma and gastric adenocarcinoma. Future studies are warranted to determine the impact of TTF on the net health outcome.

The NCCN Clinical Practice Guidelines for Pancreatic Adenocarcinoma do not reference TTF therapy as a treatment for this indication.

REGULATORY STATUS

In April 2011, the NovoTTF-100A System (Novocure; assigned the generic name of TTF) was approved by the U.S. Food and Drug Administration (FDA) through the premarket approval process. The FDA approved label reads as follows: "The NovoTTF-100A System is intended as a treatment for adult patients (22 years of age or older) with confirmed GBM, following confirmed recurrence in an upper region of the brain (supratentorial) after receiving chemotherapy. The device

is intended to be used as a stand-alone treatment and is intended as an alternative to standard medical therapy for recurrent GBM after surgical and radiation options have been exhausted."

In September 2014, FDA approved Novocure's request for a product name change from NovoTTF-110A System to Optune.

In October 2015, FDA expanded the indication for Optune in combination with temozolomide to include newly diagnosed GBM.

The device was granted priority review status in May 2015 because there was no legally marketed alternative device available for the treatment of newly diagnosed GBM, a life-threatening condition.

In July 2016, a smaller, lighter version of the Optune device, called the Optune System (NovoTTF-200A System), received FDA approval.

The FDA-approved label for newly diagnosed GBM reads as follows: "This device is indicated as treatment for adult patients (22 years of age or older) with histologically confirmed glioblastoma multiforme (GBM). Optune with temozolomide is indicated for the treatment of adult patients with newly diagnosed, supratentorial glioblastoma following maximal debulking surgery and completion of radiation therapy together with concomitant standard of care chemotherapy."

In May 2019, the FDA approved a modified version of the Optune System (NovoTTF-100A System), which is now called the Optune Lua System (NovoTTF™-100L System), for "treatment of adult patients with unresectable, locally advanced or metastatic, malignant pleural mesothelioma (MPM) to be used concurrently with pemetrexed and platinum-based chemotherapy. The indication was modified from that granted for the Humanitarian Device Exemption designation to more clearly identify the patient population the device is intended to treat and in which the safety and probable benefit of the device is supported by the available clinical data."

In September 2021, the FDA granted breakthrough designation to the NovoTTF-200T System for use together with atezolizumab and bevacizumab for the first-line treatment of patients with unresectable or metastatic liver cancer.

To date, all of the existing tumor treating fields products fall under the brand name Optune. In March 2020, the manufacturer of Optune products announced a plan to include a suffix after the brand name for newly approved indications to further delineate specific indications for individual products (e.g., Optune Lua). Optune was renamed Optune Gio in 2023.

In October 2024, the FDA approved Optune Lua as a device to be used together with PD-1/PD-L1 inhibitors or docetaxel. It is indicated for adult patients with metastatic non-small cell lung cancer (mNSCLC) who have progressed on or after a platinum-based regimen.

In February 2026, the FDA approved Optune Pax (Novocure) as a device to be used in combination with gemcitabine and nab-paclitaxel for patients with locally advanced pancreatic cancer.

The U.S. Food and Drug Administration (FDA) regulates Tumor Treating Field (TTF) Systems as medical devices. All TTF Systems including related components require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices [accessed

Background

Type 1 Diabetes Mellitus (T1DM) is one of the most common chronic childhood diseases. There is a bimodal distribution in regard to the onset-age of T1DM in children; one peak occurs at four to six years of age and a second peak occurs at 10 to 14 years of age. Although more common in children, 25% of T1DM cases are diagnosed in adults. Overall, approximately 1 million to 1.5 million Americans have T1DM. The disorder is caused by insulin deficiency following the destruction of the insulin-producing beta cells of the pancreas. This detail assists in the differentiation between T1DM and Type 2 Diabetes Mellitus (T2DM) since the latter is mostly characterized by insulin resistance as opposed to insulin deficiency.

The lifetime risk of developing T1DM is increased in close relatives of patients with the disorder. Offspring of an affected mother have a 1% to 4% increased risk, offspring of an affected father have a 3% to 8% increased risk, and offspring with both parents affected have up to a 30% increased risk. In patients that are genetically susceptible to T1DM, the exposure to environmental agents such as food or viruses can trigger the immune response that leads to the destruction of insulin-producing pancreatic beta cells. The initial diagnosis of T1DM is often made after three initial presentations: diabetic ketoacidosis (DKA), asymptomatic incidental discovery, or classic new onset of polydipsia, polyuria, weight loss with hyperglycemia, and ketonemia. T1DM can be further broken down into four stages of increasing disease progression. Details about these stages can be found in the "considerations" section of this policy.

Tzield (teplizumab) is a CD3-directed monoclonal antibody that is indicated to delay the onset of stage 3 T1DM in patients eight years of age and older with stage 2 T1DM. The efficacy of Tzield was evaluated in a prospective, randomized, placebo-controlled, double-blind, multicenter phase II clinical trial (An Anti-CD3 Antibody, Teplizumab, in Relatives at Risk for Type 1 Diabetes (NCT01030861). This study enrolled 76 participants between the ages of eight and 45 years of age. The median age was 14 in the treatment group and 13 in the placebo group. Participants included in the study did not have a diagnosis of T1DM but were classified as being high risk due to having a relative of varying degree with T1DM. Participants were randomized to receive intravenous infusions of either Tzield (n = 44) or placebo (n = 32) over 30 minutes followed by a 2-hour observation period for 14 consecutive days. This was conducted in an outpatient setting. The median follow-up period was 745 days and the duration of follow-up was > 3 years in 75% of the participants. The primary endpoint of the study was the elapsed time from randomization to the clinical diagnosis of diabetes, determined with the use of criteria from the American Diabetes Association. Scheduled oral glucose-tolerance tests (OGTT) were performed at three and six months after the infusions and every six months thereafter. OGTT results that indicated diabetes were confirmed, and the date of diagnosis was identified as the time of the first of the two diagnostic tests. The median time to T1DM diagnosis was 48.4 months in the treatment group and 24.4 months in the placebo group (HR = 0.41 [95% CI, 0.22 to 0.78, p = 0.006]). Overall, T1DM was diagnosed in 19 (43%) of the participants in the treatment group and in 23 (72%) of the participants in the placebo group. Significant adverse events that occurred during the study were lymphopenia (68% in the treatment group, 6% in the placebo group), infection with normal ANC (27% in the treatment group, 13% in the placebo group), and rash (30% in the treatment group, 0% in the placebo group). Of note, the nadir lymphocyte count occurred at day five in the treatment group and was resolved by day 45 in all participants except for one.

In June 2023, the American Diabetes Association released updates to the 2023 Standards of Care in Diabetes on the use of FDA approved therapies to delay the occurrence of T1DM. Section 2.6 states that when multiple islet autoantibodies are identified, referral to a specialized center for further evaluation and/or consideration of a clinical trial or approved therapy to potentially delay development of clinical diabetes should be considered.

Summary

Effective Date of Policy:	8/13/26
Indications	Delay the onset of stage 3 T1DM in patients eight years of age and older with stage 2 T1DM
ICD10 Diagnosis Codes	E10 (Diabetes Mellitus Type 1 diagnosis code)
HCPCS Code	J9381
Availability	2 mg/ml solution for injection
Duration	3 months to allow for 14-day treatment course

Required Criteria for Initial Approval		
All of the following conditions for the requested indication must be met in order to approve therapy:		
Specific Indication	**Inclusion Criteria**	**Recommended Dosing**

Delay the onset of stage 3 T1DM in patients eight years of age and older with stage 2 T1DM (FDA approval)
 	
ICD10: E10 (Diabetes Mellitus Type 1 diagnosis code)
	• Therapy is requested by an endocrinologist
	• Enrollee is 1 year of age or older
	• Must have a diagnosis of Stage 2 type 1 diabetes defined as (documentation must be submitted for the following):
	  ○ At least two of the following pancreatic islet autoantibodies must be confirmed
	  ▪ Glutamic acid decarboxylase 65 (GAD) autoantibodies
	  ▪ Insulin autoantibody (IAA)
	  ▪ Insulinoma-associated antigen 2 autoantibody (IA-2A)
	  ▪ Zinc transporter 8 autoantibody (ZnT8A)
	  ▪ Islet cell autoantibody (ICA)
	  ○ Dysglycemia without overt hyperglycemia as determined by oral glucose tolerance testing (OGTT), confirmed on two separate occasions within the previous 7 weeks. Note: Individuals < 18 years of age only require a single abnormal OGTT result within the previous 7 weeks.
	  ▪ Fasting blood glucose between 110 mg/dL and 125 mg/dL OR
	  ▪ 2-hour post-prandial glucose ≥ 140 mg/dL and < 200 mg/dL OR
	  ▪ 30-, 60-, or 90-minute value on OGTT ≥200 mg/dl
	• Prescriber must attest that the patient does not have clinical history that suggests type 2 diabetes AND
	• Tzield will not be covered for use in patients with Stage 3 Type 1 diabetes
	  ○ Although the phase 3 PROTECT trial met its primary endpoint, demonstrating significantly higher stimulated C-peptide levels in Tzield treated patients than placebo at week 78 (least-squares mean difference, 0.13 pmol/mL; 95% confidence interval [CI], 0.09 to 0.17; P<0.001), there was no significant difference observed in secondary endpoints. These secondary endpoints included mean daily insulin dose, the mean daily percentage of time in the target glucose range, the change from baseline in the mean hemoglobin A1c (HbA1c), and clinically important hypoglycemic events. Further studies are needed to confirm clinical benefit of Tzield in Stage 3 Type 1 diabetes. Of note, the confirmatory Phase 3 trial, βETA PRESERVE, has been initiated to assess HbA1c and prandial insulin use with Tzield compared to placebo in patients with recently diagnosed Stage 3 Type 1 diabetes.
	• Tzield will not be covered for any other non-FDA approved indication
	
	All other requests will be considered off-label/ investigational and will not be covered.
		• Tzield is administered by intravenous infusion (over a minimum of 30 minutes), using a body surface area-based dosing, once daily for 14 consecutive days.
		• See package insert for complete dosing and administration.

Continuation Criteria
• Coverage will be limited to a single cycle of 14 consecutive infusions, additional cycles of infusions will not be eligible for coverage. • Retreatment beyond a 14-day treatment course will be considered experimental/investigational and will not be authorized.

Considerations

- Prior authorization is obtained through the CDPHP pharmacy department.

Stages of T1DM

Stage 1	Beta cell autoimmunity (≥ 2 islet autoantibodies), normal blood glucose, and presymptomatic
Stage 2	Beta cell autoimmunity (≥ 2 islet autoantibodies), raised blood glucose, and presymptomatic
Stage 3	Beta cell autoimmunity (≥ 2 islet autoantibodies), raised blood glucose, and symptomatic
Stage 4	Longstanding disease

CDPHP Pharmacy Services 8/13/2026

New: 12/14/2022

Revised	Reviewed
12/23, 9/25, 6/26, 8/26	12/24

Revision Date	Changes Made
12/22	New policy
12/23	Removed inclusion criteria: enrollee has a direct relative with a diagnosis of T1DM Clarified exclusion criteria: enrollee must not have any symptoms associated with stage 3 T1DM
9/25	Removed upper age limit of 45 years of age Updated language for dysglycemia Removed exclusion criteria Updated duration of authorization to 3 months
6/2026	Revised age for FDA expanded indication
8/2026	Updated language regarding Stage 3 Type 1 diabetes

MEDICAL POLICY

Medical Policy Title	**Urine Drug Testing**
Policy Number	**2.02.50**
Current Effective Date	**June 1, 2026**
Next Review Date	**October 2026**

Our medical policies are based on the assessment of evidence based, peer-reviewed literature, and professional guidelines. Eligibility for reimbursement is based upon the benefits set forth in the member's subscriber contract. (Link to Product Disclaimer)

POLICY STATEMENT(S)

Presumptive Drug Testing for Pain Management

I. Presumptive (immunoassay) urine drug testing, in office or at point-of-care, for outpatient pain management, is considered **medically appropriate** for:

   A. Baseline screening before initiating treatment or at the time treatment is initiated when **ALL** of the following conditions are met:

      1. An adequate clinical assessment of patient history and risk of substance use disorder (SUD) is performed;
      2. Clinicians have knowledge of test interpretation; **and**
      3. There is a plan in place regarding how to use test findings clinically; **or**

   B. Subsequent monitoring of treatment at a frequency appropriate for the risk level of the individual patient (please refer to Policy Guidelines).

Presumptive Drug Testing for Substance Use Treatment

II. Presumptive (immunoassay) urine drug testing, in office or at point-of-care, for outpatient substance use treatment, is considered **medically appropriate** for:

   A. Baseline screening before initiating treatment or at the time treatment is initiated, one time per program entry when **ALL** of the following conditions are met:

      1. An adequate clinical assessment of patient history and risk of substance use disorder is performed;
      2. Clinicians have knowledge of test interpretation; **and**
      3. There is a plan in place regarding how to use test findings clinically; **or**

   B. Subsequent monitoring of treatment, either during a stabilization or maintenance phase at a frequency appropriate for the risk level of the individual patient (please refer to Policy Guidelines).

Definitive Drug Testing for Pain or Substance Use

III. Definitive urine drug testing, in outpatient pain management or substance use treatment, is considered **medically appropriate** in **ANY** of the following circumstances:

A. When presumptive urine drug testing is unable to identify the following:
    1. A specific substance or metabolite;
    2. Specific drugs in a large family of drugs;
    3. A specific substance or metabolite that is not detectable by qualitative urine drug testing (e.g., fentanyl, meperidine, synthetic cannabinoids);
    4. A negative qualitative urine drug test result (or to confirm a positive result) that is inconsistent with a patient's self-report, presentation, medical history, or current prescribed pain medication plan; **or**
    5. A non-prescribed medication or illicit use, to ensure the safe ongoing prescription of controlled substances;

B. When a definitive concentration of a drug is needed to guide management (e.g., discontinuance of THC use according to a treatment plan);

C. To rule out an error as the cause of a qualitative urine drug testing result;

D. When used as part of a differential assessment of medication efficacy, side effects, or drug-drug- interactions.

RELATED POLICIES

Corporate Medical Policy:

Out of Network Care, 1370/20.000145

POLICY GUIDELINE(S)

I. Testing frequency is dependent on the stability of the patient, the type of treatment, the treatment setting and the half-life of drugs in the matrix being tested.

II. Full informed consent is a requirement before urine drug testing. Patients should be informed of the specific drug testing protocol before treatment and should provide written agreement with the plan for monitoring. As stated in a joint U.S. Veterans Affairs/Department of Defense guideline, patients' refusal to consent to urine testing should be considered as one factor in the overall assessment of patients' ability to adhere to treatment.

III. Testing should be performed randomly or selectively based on patient history.

IV. Testing should not be performed as part of standard protocols (e.g., routine standing orders).

V. Testing should be supported by both an order for the test and rationale for the testing.

VI. The medical record should include documentation that the results were reviewed and will impact patient care.

VII. Presumptive urine drug testing for opioid pain management should be part of the pain management strategy and may be performed as follows:

    A. Prior to initiating opioid therapy.

B. Every three (3) months to assess effectiveness of the prescribed dose and decisions regarding tapering or increasing the dose are planned.

C. At least annually.

VIII. For end-of-life pain management with opioids, testing is indicated if there is any reason to consider diversion of the drug (lost scripts, lost pills, enormous escalation of utilization without member appearing to have consumed the specific amount of opioids).

IX. Frequency of presumptive urine drug testing for substance use disorder is based on the consecutive days of abstinence as follows:

A. 0 to 30 days consecutive abstinence: One (1) to three (3) presumptive urine drug tests per week. Requests for coverage of more than three (3) presumptive urine drug tests per week must be accompanied by clinical documentation to support additional testing.

B. 31 to 90 consecutive days of abstinence: One (1) to three (3) presumptive urine drug tests per week. Requests for coverage of more than three (3) presumptive urine drug tests per week must be accompanied by clinical documentation to support additional testing.

C. Greater than 90 consecutive days of abstinence: One (1) to three (3) presumptive urine drug tests per month.

1. Requests for coverage of more than three (3) physician-directed presumptive urine drug tests in one (1) month must be accompanied by clinical documentation to support additional testing. (e.g., Contingency management in SUD is over a 10-week to 12-week period.)

X. Definitive urine drug testing for opioid pain management may be performed to detect specific opioids that cannot be identified on standard immunoassays or in the event of unexpected urine drug test results.

XI. Frequency of definitive urine drug testing and the rationale for testing must be documented in the patient's medical record. Frequency is based on the following consecutive days of abstinence, as follows:

A. Zero (0) to 30 days consecutive days of abstinence: One (1) physician-directed testing profile per week. Requests for coverage of more frequent definitive urine drug tests in one (1) week must be accompanied by clinical documentation to support additional testing.

B. 31 to 90 consecutive days of abstinence: One (1) to three (3) physician-directed testing profile(s) per month. Requests for coverage of more than three (3) definitive urine drug tests in one month must be accompanied by clinical documentation to support additional testing.

C. Greater than 90 consecutive days of abstinence: One (1) to three (3) physician-directed testing profile(s) per three-month period. Requests for more than three (3) definitive urine drug tests in a three-month period must be accompanied by clinical documentation to support additional testing.

Proprietary Information of Capital District Physicians' Health Plan, Inc. | CDPHP Universal Benefits,® Inc. | Capital District Physicians' Healthcare Network, Inc.

XII. Frequency of urine drug testing for individuals on chronic opioid therapy depends on the risk of opioid misuse and/or the existence of an opioid disorder. Frequency of testing ranges from:

A. Low risk: One (1) to two (2) times per twelve (12) month period

B. Moderate risk: One (1) to two (2) times per six (6) month period

C. High risk: One (1) to three (3) times per three-month period for prescribed medications, non-prescribed medications that may pose a safety risk if mixed with prescribed medications, and illicit substances based on patient history, clinical presentation and/or community usage.

DESCRIPTION

Drug testing is a vital part of addiction assessment and treatment planning, especially when combined with other clinical tools like substance use history, physical and mental evaluations, withdrawal severity scores, and standardized lab assessments (ASAM, 2013). Skilled clinicians use drug testing to verify self-reports, confirm diagnoses, identify denial or minimization, enhance treatment motivation, monitor progress, and validate abstinence or adherence to prescribed medications. Contingency management, which rewards abstinence, is one example of an effective intervention. Urine drug testing is especially important during the intensive "primary treatment" phase, which includes psychosocial support, psychoeducation, psychotherapy, and cognitive-behavioral strategies. Random and frequent testing should be maintained throughout this phase. In the post-treatment monitoring phase, continued random testing remains central, supporting long-term recovery and abstinence. Testing should be unpredictable and more frequent early in treatment, with reduced frequency as abstinence stabilizes. Varying the testing panels and methods further strengthens its effectiveness.

<u>Categories of Urine Drug Testing</u>

- Presumptive Drug Testing (Screening) detects the presence or absence of drugs in urine when immediate results are needed for patient care. Common methods include immunoassays (IA) and thin layer chromatography (TLC). IAs, which can be lab-based or point-of-care (e.g., a physician's office), use antibodies to detect drugs through competitive binding. The amount of labeled drug that binds to the antibody is inversely related to the drug concentration in the sample.

  IA formats include cups, dipsticks, cassettes, or strips, read visually or with instruments. They vary in specificity—some detect individual drugs, others only drug classes—and may miss structurally similar substances. Cross-reactivity with other medications is possible but less common due to improved antibodies.

  The most common test, SAMHSA-5 panel tests for amphetamines, THC, cocaine, opiates (e.g., codeine, morphine), and PCP. Panels can be expanded to include benzodiazepines and synthetic/semi-synthetic opioids like oxycodone, buprenorphine, and methadone. Results are qualitative—positive (above threshold) or negative (below threshold)—and do not confirm drug absence. IA tests offer rapid results: minutes for onsite, 1–4 hours for lab-based.

- Definitive (Confirmatory) Testing identifies specific drugs and metabolites by analyzing their

molecular structures. It confirms results from screening evaluates and detects substances not identifiable by immunoassays (IAs). These lab-based tests quantify drug levels in urine and report exact concentrations.

Common methods include:

- Gas Chromatography-Mass Spectrometry (GC-MS): The gold standard for confirmatory testing. It separates and identifies compounds but typically requires prior specification of target drugs. Turnaround is several days.
- Liquid Chromatography-Tandem Mass Spectrometry (LC-MS/MS): Faster and easier than GC-MS, it uses two mass spectrometers for enhanced detection without needing derivatization.
- Quantitative or confirmation testing can be performed as a reflex test which is performed after an initial test result to identify further diagnostic information.

Urine drug tests are vulnerable to tampering, including dilution (e.g., excessive water intake), commercial adulterants, and synthetic urine. Some tampering can be detected through visual inspection or onsite checks of temperature, creatinine, and specific gravity.

Accurate interpretation requires understanding drug metabolites and manufacturing byproducts. For example, trace hydrocodone in patients prescribed oxycodone may be acceptable due to manufacturing impurities.

Urine testing is commonly used at treatment initiation to assess current drug use. While routine universal screening may detect more misuse and reduce stigma, it can strain healthcare resources and affect trust. Selective testing based on risk assessment is an alternative. Protocols vary, some confirm all positive qualitative results with quantitative tests, while others confirm only unexpected results or those involving drugs with unreliable immunoassays.

SUPPORTIVE LITERATURE

Choucair et al (2024) studied the use of DART-MS/MS as a faster and more efficient alternative to traditional opioid detection methods in clinical laboratories. Current practices typically involve IA screening followed by LC-MS/MS confirmation, which, while accurate, are time-consuming and require extensive sample preparation. The researchers optimized DART-MS/MS by adjusting variables like temperature, extraction methods, and hydrolysis times, and evaluated its performance across 12 opioids. The method demonstrated high sensitivity and specificity for several opioids, including fentanyl, codeine, and hydrocodone, but was less effective for others like morphine and oxycodone. The study concludes that DART-MS/MS shows promise as a rapid, quantitative tool for opioid testing in urine, though further research is needed to broaden its clinical applications.

Magura et al (2023) investigated the comparative effectiveness of two drug testing methodologies—presumptive testing and direct-to-definitive testing—using two biological matrices: oral fluid and urine. A total of 1098 samples (urine and oral fluid) from individuals applying for methadone treatment were collected. All samples were evaluated via IA and LC-MS/MS. Presumptive testing, typically performed with IA, offers rapid screening but is susceptible to false positives and negatives due to limited specificity and cross-reactivity. Direct-to-definitive testing, using advanced techniques

like LC-MS/MS, provides highly accurate identification of drug compounds without the need for preliminary screening. The study analyzes a national sample of individuals misusing drugs to evaluate detection windows, analyte coverage, and diagnostic accuracy across both matrices. Urine testing is traditionally favored for its longer detection window and regulatory acceptance, while oral fluid testing is less invasive and better suited for detecting recent drug use. The findings aim to inform clinical and forensic toxicology practices by highlighting the trade-offs between speed, accuracy, and operational efficiency in drug testing protocols.

PROFESSIONAL GUIDELINE(S)

The American Society for Addiction Medicine (ASAM) updated its guidelines on Appropriate Use of Drug Testing in Clinical Addiction (2017). The guidelines include the following recommendations:

- Drug testing should be used widely in addiction treatment settings because evidence suggests that drug testing assists with monitoring adherence and abstinence in treatment and can improve patient outcomes and should be used in combination with a patient's self-reported information about substance use. Providers should understand that drug tests are designed to measure whether a substance has been used within a particular window of time and drug testing panels should be based on the patient's drug of choice, prescribed medications, and drugs commonly used in the patient's geographic location and peer group.
- Presumptive testing should be a routine part of initial and ongoing patient assessment, as it can provide more immediate (albeit less accurate) results. Definitive testing techniques should be used whenever a provider wants to detect specific substances not identified by presumptive methods, to quantify levels of the substance present, and to refine the accuracy of the results; and the results inform clinical decisions that have major clinical or non-clinical implications for the patient (e.g. treatment transition, changes in medication therapies, changes in legal status).
- For people in addiction treatment, frequency of testing should be dictated by patient acuity and level of care, and providers should look to tests' detection capabilities and windows of detection to determine the frequency of testing. Providers should understand that increasing the frequency of testing increases the likelihood of detection of substance use, but there is insufficient evidence that increasing the frequency of drug testing has an effect on substance use, itself.
- Drug testing should be scheduled more frequently (at least weekly) at the beginning of treatment, and the frequency should be decreased to monthly as recovery progresses and is stable.
- Testing should occur on a random schedule in outpatient services following weekends, holidays, and paydays, when feasible because the patient's opportunity for substance use is greater relative to residential treatment. Additional drug testing should be considered if a patient is experiencing stressful psychological events.

The ASAM published a public policy statement on the Ethical Use of Drug Testing in The Practice of Addiction Medicine in 2019. The statement included the following recommendations:

- Drug testing is recommended as a therapeutic tool in evidence-based addiction treatment. It

should not be used or presented as a punitive measure.

- Drug testing should be used only when clinically necessary. Tests should be selected based on an individualized clinical assessment of the patient and performed after informed consent whenever possible.
- Presumptive testing should be a routine part of initial and ongoing patient assessment.
- Definitive testing may be used when the results will alter the care plan or to detect specific substances not identified by presumptive methods and to refine the accuracy of the test results.
- It is inappropriate to order definitive testing for all analytes in every drug test conducted on a patient.
- Clinicians should ensure that drug test results remain confidential.
- Clinicians ordering drug tests should be aware of the costs of different testing methods and the financial burden that the patient and society may incur.
- If clinicians responsible for making clinical decisions based on drug test results do not have training in toxicology, collaboration should occur with a toxicologist or an individual with Medical Review Officer certification.
- Clinicians should maintain knowledge of state or federal rules or guidelines about drug testing that may apply to their practice.
- It is unethical for clinicians or addiction treatment programs to ask laboratories to change cutoff levels to improve that provider's quality metrics.
- It is unethical to provide or receive incentives for the use of drug testing independent of a clinical rationale.

The ASAM published a National Practice Guideline for the Treatment of Opioid Use Disorder (2020) which identifies the following:

- Urine drug testing can be used during assessment and diagnosis to validate patient self-reported information and to identify poly-substance use.
- Testing can be used to monitor patients for adherence to medication and for use of illicit and controlled substances during treatment.
- The frequency of drug testing is determined by a number of factors including the stability of the patient, type of treatment and treatment setting. The guideline also notes that no further clarification was found in the literature related to urine drug testing and this is considered a gap in literature.

The American Society of Interventional Pain Physicians (ASIPP) 2023 updated guidelines for opioids for chronic noncancer pain and made the following recommendations for urine drug testing:

- Urine drug monitoring (UDM) should be implemented at the initiation of opioid therapy and conducted periodically for monitoring therapeutic compliance as per available guidance referential to mode and frequency of testing. (Evidence Level: Moderate; Strength of

Recommendation: Strong).

- Tapering or weaning processes must be initiated slowly after appropriate criteria have been met and should entail slow tapering of the dosage across a specified period of time. Reinstitution of opioid therapy can be considered when such treatment is deemed medically necessary if the patient's behavior and pattern of drug use are shown to be stable, and if results of at least two consistent urine drug tests are negative (for opioids and/or illicit drugs). (Evidence Level: Moderate; Strength of Recommendation: Moderate).
- Adherence monitoring to assess and sustain appropriate use must be instituted at proper intervals, as based on risk stratification and indication(s) of other issues that may be regarded as negatively influencing therapeutic compliance. Evidence Level: Moderate; Strength of recommendation: Moderate

In 2014, the American College of Occupational and Environmental Medicine (ACOEM) updated its guidelines for Opioids for Treatment of Acute Subacute, Chronic, and Postoperative Pain chronic use of opioids and recommends:

- Baseline and random urine drug screening, qualitative and quantitative, for patients prescribed opioids for the treatment of subacute or chronic pain to evaluate presence or absence of the drug, its metabolites and other substance(s) use. In certain situations, other screenings (e.g., hair particularly for information regarding remote use or blood) (for acute toxicity) may be appropriate. (C; High Confidence).

The Centers for Disease and Control Prevention (CDC) Guideline for Prescribing Opioids for Chronic Pain (2016) recommends:

- When prescribing opioids for chronic pain, clinicians should use urine drug testing before starting opioid therapy and consider urine drug testing at least annually, to assess for prescribed medications, as well as other controlled prescription drugs and illicit drugs (recommendation category: B, evidence type 4).
- If clinicians suspect their patient might be sharing or selling opioids and not taking them, clinicians should consider urine drug testing to assist in determining whether opioids can be discontinued without causing withdrawal. A negative drug test for prescribed opioids might indicate the patient is not taking prescribed opioids, although clinicians should consider other possible reasons for this test result.
- Experts agreed that, prior to starting opioids for chronic pain, and periodically during opioid therapy, clinicians should use urine drug testing to assess for prescribed opioids, as well as other controlled substances and illicit drugs that increase the risk for overdose when combined with opioids, including nonprescribed opioids, benzodiazepines, and heroin.
- Most Experts agreed that urine drug testing at least annually for all patients was reasonable. Some experts noted that this interval might be too long in some cases and too short in others, and that the follow-up intervals should be left to the discretion of the clinician.
- In most situations, initial urine drug testing can be performed with a relatively inexpensive IA

panel for commonly prescribed opioids and illicit drugs. Patients who are prescribed less-commonly-used opioids might require specific testing for those agents. The use of confirmatory testing adds substantial costs and should be based on the need to detect specific opioids that cannot be identified on standard IAs or on the presence of unexpected urine drug test results.

- Clinicians should not test for substances for which results would not affect patient management or for which implications for patient management are unclear.
- Clinicians should be familiar with the drugs included in urine drug testing panels used in their practice and should understand how to interpret results for these drugs. Before ordering urine drug testing, clinicians should have a plan for responding to unexpected results.
- Clinicians should explain to patients that urine drug testing is intended to improve their safety, they should also explain expected results (e.g., presence of prescribed medication and absence of drugs, including illicit drugs, not reported by the patient).
- Clinicians should ask patients about use of prescribed and other drugs and ask whether there might be unexpected results. This will provide an opportunity for patients to provide information about changes in their use of prescribed opioids or other drugs.
- Clinicians should use unexpected results to improve patient safety (e.g., changing in pain management, tapering or discontinuing opioids, re-evaluating more frequently, offering naloxone, or referring for treatment for substance use disorder, all as appropriate). If tests for prescribed opioids are repeatedly negative, confirming that the patient is not taking the prescribed opioid, clinicians can discontinue the prescription without a taper.
- Clinicians should not dismiss patients from care based on a urine drug test result because this could constitute patient abandonment and could have adverse consequences for patient safety.

CPT Codes

Code	Description
80305	Drug test(s), presumptive, any number of drug classes, any number of devices or procedures; capable of being read by direct optical observation only (e.g., utilizing immunoassay [e.g., dipsticks, cups, cards, or cartridges]), includes sample validation when performed, per date of service
80306	Drug test(s), presumptive, any number of drug classes, any number of devices or procedures; read by instrument assisted direct optical observation (e.g., utilizing immunoassay [e.g., dipsticks, cups, cards, or cartridges), includes sample validation when performed, per date of service
80307	Drug test(s), presumptive, any number of drug classes, any number of devices or procedures; by instrument chemistry analyzers (e.g., utilizing immunoassay [e.g., EIA, ELISA, EMIT, FPIA, IA, KIMS, RIA]), chromatography (e.g., GC, HPLC), and mass spectrometry either with or without chromatography (e.g., DART, DESI, GC-MS, GCMS/MS, LC-MS, LC-MS/MS, LDTD, MALDI, TOF) includes sample validation when performed, per date of service
80320-80373	Definitive drug testing (code range)
80375	Drug(s) or substance(s), definitive, qualitative or quantitative, not otherwise specified; 1-3 analytes
80376	Drug(s) or substance(s), definitive, qualitative or quantitative, not otherwise specified; 4-6 analytes
80377	Drug(s) or substance(s), definitive, qualitative or quantitative, not otherwise specified; 7 or more analytes
83992	Phencyclidine (PCP)
0007U	Drug test(s), presumptive, with definitive confirmation of positive results, any number of drug classes, urine, includes specimen verification including DNA authentication in comparison to buccal DNA, per date of service (ToxProtect, Genotox Laboratories, Ltd)
0051U	Prescription drug monitoring, evaluation of drugs present by liquid chromatography tandem mass spectrometry (LC-MS/MS), urine or blood, 31 drug panel, reported as quantitative results, detected or not detected, per date of service (UCompliDx, Elite Medical Laboratory Solutions, LLC)

Code	Description
0082U	Drug test(s), definitive, 90 or more drugs or substances, definitive chromatography with mass spectrometry, and presumptive, any number of drug classes, by instrument chemistry analyzer (utilizing immunoassay), urine, report of presence or absence of each drug, drug metabolite or substance with description and severity of significant interactions per date of service (NextGen Precision™ Testing, Precision Diagnostics LBN Precision Toxicology, LLC)
0093U	Prescription drug monitoring, evaluation of 65 common drugs by LC-MS/MS, urine, each drug reported detected or not detected (ComplyRX, Claro Labs)
0117U	Pain management, analysis of 11 endogenous analytes (methylmalonic acid, xanthurenic acid, homocysteine, pyroglutamic acid, vanilmandelate, 5-hydroxyindoleacetic acid, hydroxymethylglutarate, ethylmalonate, 3-hydroxypropyl mercapturic acid (3-HPMA), quinolinic acid, kynurenic acid), LC-MS/MS, urine, algorithm reported as a pain-index score with likelihood of atypical biochemical function associated with pain (Foundation PI℠, Ethos Laboratories)
0227U	Drug assay, presumptive, 30 or more drugs or metabolites, urine, liquid chromatography with tandem mass spectrometry (LC-MS/MS) using multiple reaction monitoring (MRM), with drug or metabolite description, includes sample validation (Comprehensive Screen, Aspenti Health)
0328U	Drug assay, definitive, 120 or more drugs and metabolites, urine, quantitative liquid chromatography with tandem mass spectrometry (LC-MS/MS), includes specimen validity and algorithmic analysis describing drug or metabolite and presence or absence of risks for a significant patient-adverse event, per date of service (CareView360, Newstar Medical Laboratories LLC)
0603U	Drug assay, presumptive, 77 drugs or metabolites, urine, liquid chromatography with tandem mass spectrometry (LC-MS/MS), results reported as positive or negative

MEDICAL POLICY

Medical Policy Title	**Vagus Nerve Stimulation and Vagus Nerve Blocking Therapy**
Policy Number	**7.01.05**
Current Effective Date	**August 20, 2026**
Next Review Date	**August 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

This policy does not address transcutaneous vagus nerve stimulation. Refer to CMP 1.01.61 Non-Invasive Surface Electrical Stimulation for Pain and Rehabilitation.

POLICY STATEMENT(S)

I. An implantable vagus nerve stimulation (VNS) device is **medically appropriate** when used as a treatment for medically refractory seizures.

II. An implantable VNS device is **investigational** as a treatment for individuals with depression or any other non-epileptic conditions (e.g., heart failure, fibromyalgia, tinnitus, traumatic brain injury, essential tremor, headache, post-stroke).

III. Vagus nerve stimulation implants that allow detection and stimulation based on increased heart rate (e.g., AspireSR Model) are **investigational** for **ALL** indications.

IV. Vagus nerve blocking therapy is **investigational** as a treatment for individuals with morbid obesity.

DESCRIPTION

Seizures have been defined as paroxysmal disorders of the central nervous system characterized by abnormal cerebral neuronal discharge, with or without loss of consciousness. Medically refractory seizures are defined as seizures that occur in spite of therapeutic levels of antiepileptic drugs or seizures that cannot be treated with therapeutic levels of antiepileptic drugs because of intolerable adverse effects of these drugs.

The goal of epilepsy surgery is to either remove the seizure-producing area of the brain or to limit the spread of seizure activity. Surgical results can be considered curative (stopping the seizures) or palliative (restricting the spread of the seizures). The type of surgery performed is dependent on the type of seizure and where the seizures begin in the brain. Curative procedures (e.g., temporal lobectomy, cortical excision, hemispherectomy) are performed when tests consistently point to a specific area of the brain where the seizures begin. Palliative procedures (e.g., corpus callosotomy, subpial transections) are performed when a seizure focus cannot be determined, or it overlaps brain areas critical for speech, movement, or vision.

The vagus nerve extends from the brain down the side of the neck to the large intestines, helping regulate key body systems such as the heart and digestion. A vagus nerve stimulator device (VNS) is a device used as an add-on therapy for individuals with epilepsy that is not well controlled by medication. It delivers mild electrical impulses to the vagus nerve targeting areas of the brain involved in seizure activity. VNS is especially important for individuals whose seizures do not respond to drug therapy, who are not candidates for epilepsy surgery, or for whom surgery has failed to significantly reduce sized frequency.

Surgery for implantation of a vagus nerve stimulator involves wrapping two spiral electrodes around the left vagus nerve within the carotid sheath. The electrodes are connected to an infraclavicular generator pack. The programmable stimulator may be programmed in advance, to stimulate at regular times or upon demand by the individual or caregiver by placing a magnet against the subclavicular implant site.

VNS is also being investigated for a variety of other non-epileptic conditions, including depression that has not responded to conventional treatment, bipolar disorder, obesity, autism, essential tremor, refractory anxiety, cluster headaches/migraines, bulimia, stroke, and Alzheimer's disease.

The vagus nerves play a significant role in food processing, in signaling the feeling of fullness, and in prolonging the absence of hunger through nervous control of multiple functions. Vagal blocking (VBLOC), therapy is being developed to induce intermittent intra-abdominal vagal blocking to treat obesity, using high-frequency electrical currents. The electrodes are positioned laparoscopically on the anterior and posterior vagal trunks near the esophagogastric junction (EGJ), without anatomic modification or tissue compression of the alimentary tract. Blocking vagus nerve signals may reduce appetite and create weight loss by limiting the expansion of the stomach*;* and by reducing the frequency and intensity of stomach contractions. Vagal blocking therapy may also reduce the absorption of calories by decreasing the secretion of digestive enzymes. When the blocking is paused, two-way neural signals resume, and the stomach and pancreas return to normal function.

Vagal blocking therapy's intermittent active therapeutic episodes are programmed for twelve hours per day, to prevent the body's natural tendency to circumvent the blocked neural signals and prolong the therapeutic effect during the individual's waking hours.

SUPPORTIVE LITERATURE

Vagus Nerve Stimulation for Focal Epilepsy

Panebianco et al (2022) updated the original 2015 review on the effectiveness of VNS as an add-on treatment for individuals with drug resistance focal epilepsy. The analysis included data from 439 participants and assessed treatment withdrawals, adverse effect, quality of life (QOL), cognition, mood, overall risk ratio for those who experience greater reduction in seizure frequency. The authors did not identify any new studies for this update thereby concluding the result are unchanged. VNS appears to be an effective treatment for individuals with intractable focal epilepsy. High level simulation was associated with greater reduction in seizure frequency compared to low level stimulation. Common side effects include voice alteration, hoarseness, pain, shortness of breath, cough, nausea, tingling sensations, headache, and infection at the surgical site. Shortness of breath, voice changes, and hoarseness occurred more frequently with high level stimulation. However, the evidence on both the effectiveness and side effects of the VNS therapy is limited and imprecise due to the small number of studies and participants, as well as gaps in trial designs and reporting. The certainty of evidence was rated as moderate to low meaning that future research is likely or very likely to impact confidence in these findings and may change the estimates.

Hamilton et al (2018) evaluated the efficacy of the AspireSR VNS, (including cardiac based seizure detection [CBSD]) by comparing outcomes in individuals receiving new AspireSR implants, and those individuals who underwent a battery replacement of AspireSR from an older VNS model. The results showed that the new implant group (AspireSR as first VNS) had a reduction in median seizures per year reduced from 192 to 64 and 59% experienced ≥50% reduction in seizures. A total of 41% saw greater than 80% reduction, 6% became seizure free during follow up, and 10% reported no anti-epileptic benefit. The battery replacement group (previously VNS to ApsireSR) showed a seizure reduction from 336 pre-VNS to 90 (post initial VNS) to 72 (post AspireSR). After the AspireSR upgrade, 71% achieved ≥50% additional reduction, and 74% required no change in stimulation duty cycle. Improvement was significantly greater from original VNS. Minimal surgical complications were reported, four cases of transient vocal cord paresis (2.6%), one lead migration (0.7%), and no infections or hemorrhage reported. Overall authors reported that AspireSR AutoStim feature (ictal tachycardia detection) provided significant value over traditional VNS.

VNS for Limb Dysfunction after Stroke

The evidence on VNS for treatment of upper-limb impairment due to stroke consists of 3 small RCTs and a systematic review that pooled their data. Two RCTs compared VNS plus rehabilitation to rehabilitation alone. Dawson et al (2016) conducted a randomized pilot trial of VNS in patients (n=21) with upper-limb dysfunction after ischemic stroke, which failed to show significant improvements for the VNS group on response and function outcomes. Dawson et al (2021) conducted a similar RCT with a larger patient population (n=106), which found a significant

difference in response and function outcomes. The third RCT compared VNS to sham (n=17) found that although VNS significantly improved response rate, there were 3 serious adverse events related to surgery (Kimberley et al 2019).

Ramos-Castaneda et al (2022) published a systematic review evaluating VNS on upper limb motor recovery after stroke, reporting that implanted VNS improved upper limb motor function based on Fugl-Meyer Assessment-Upper Extremity (FMA-UE) score when compared to control. This systematic review and meta-analysis concluded that VNS together with physical rehabilitation improves upper limb motor function in stroke patients; however, with several knowledge gaps and limitations, the authors acknowledge that more studies are needed to evaluate the efficacy.

Results from other pilot studies suggest that VNS might induce weight loss in obese patients and improve cognitive function in patients with Alzheimer's disease. However, these findings need to be validated in large, randomized, placebo-controlled trials with long-term outcomes reported.

VNS for Depression

Conway et al (2025) evaluated the safety and efficacy of the Food and Drug Administration (FDA) approved adjunctive VNS in adults with marked treatment resistant depression (TRD). The study consisted of a 12-month, double-blind multi center randomized sham-controlled trial that included 493 adults with TRD. Participants were randomized to either active VNS plus treatment as usual (Tau) or no-stimulation sham VNS therapy prior to device implantation and activation. The primary outcome was percentage of time in response from months 3 to 12, with response defined as a ≥50 % reduction from baseline on the Montgomery-Åsberg Depression Rating Scale (MADRS). Overall, 88.4% of participants completed the trial. The percentage of time in MADRS define response, did not significantly differ between the active and sham VNS groups. However, ratings from on-site clinicians (Clinical Global Inventory–Impression [CGI-I]), patients (Quick Inventory of Depressive Symptomology–Self Report [QIDS-SR]), and offsite masked raters (Quick Inventory of Depressive Symptomology–Clinician [QIDS-C]) revealed antidepressant benefits significantly favoring active VNS. Researchers concluded that although the primary outcome (percentage time in MADRS response) did not significantly differentiate VNS from sham, multiple secondary measures showed statistically and clinically significant improvements in patients receiving active VNS. Overall, the study supports VNS as a safe and moderately effective adjunctive treatment for patients with marked TRD especially when partial improvements are clinically meaningful.

Vagus Nerve Blocking Therapy

The current literature is insufficient to determine the overall safety and efficacy of treating obesity using vagal nerve blocking therapy. A randomized controlled clinical trial, EMPOWER, (MG Sarr et al 2012) found that VBLOC therapy to treat morbid obesity was safe overall; however, the weight loss was not any greater in the treatment group compared to the control group.

In the 2014 ReCharge trial, S Ikramuddin and colleagues conducted a randomized, double-blind, sham-controlled clinical trial to evaluate the effectiveness and safety of intermittent, reversible vagal nerve blockade therapy for obesity treatment. This study involved 239 participants who had a BMI of 40 to 45 or 35 to 40 and one or more obesity-related condition. It was conducted at ten sites in the

United States and Australia. Of the initial 239 participants, 157 patients received an active vagal nerve block device, and 75 received a sham device. All participants received weight management education. The coprimary efficacy objectives were to determine whether the vagal nerve block was superior in mean percentage excess weight loss to sham by a 10-point margin with at least 55% of patients in the vagal block group achieving a 20% loss and 45% achieving a 25% loss. The authors concluded that, among patients with morbid obesity, the use of vagal nerve block therapy compared with a sham control device did not meet either of the prespecified coprimary efficacy objectives, although weight loss in the vagal block group was statistically greater than in the sham device group. The treatment was well-tolerated, having met the primary safety objective.

The ReCharge trial 24-month outcomes were reported by Apovian et al (2017). At 24-months, participants (n=123) remaining in the trial had a mean excess weight loss (EWL) of 21%; mean total weight loss (TWL) of 8%; 58% had ≥ 5% TWL; and 34% had ≥ 10% TWL. Significant improvements ($p<0.05$) were seen in mean LDL, HDL, triglycerides, and systolic and diastolic blood pressures. Adverse events were reported as mild or moderate, with the most frequently reported related adverse events were heartburn and dyspepsia, neuroregulator site pain, nausea, belching, and dysphagia. Study limitations include short-term follow-up, missing data, lack of a blinded control group, and small study size.

PROFESSIONAL GUIDELINE(S)

The American Academy of Neurology reaffirmed their 2013 guidelines addressing vagus nerve stimulation for the treatment of epilepsy. The recommendations include the following guidance:

- VNS may be considered as adjunctive treatment for children with partial or generalized epilepsy (Level C, 14 Class III studies).
- VNS may be considered in patients with Lennox-Gastaut syndrome (LGS) (Level C, 4 Class III studies). The responder rate for patients with LGS does not appear to differ from that of the general population of patients with medication-resistant epilepsy.
- In adult patients receiving VNS for epilepsy, improvement in mood may be an additional benefit (Level C, 2 Class III studies).
- VNS may be considered progressively effective in patients over multiple years of exposure (Level C, 2 Class III studies).

The National Institute for Health and Carel Excellence (NICE) 2020 guidelines for implanted vagus nerve stimulation for treatment-resistant depression recommends the following guidance:

- Evidence suggests that animplanted VNS for treatment-resistant depression does not raise significant safety concerns though it is associated with common well known side effects. However, the evidence supporting its effectiveness is of limited quality. As a result, the use of this procedure should be restricted to a setting with appropriate clinical governance, informed consent processes, and provisions for audit or research.

The American Psychological Association (APA) clinical practice guideline addressing the treatment of depressive disorders in children, adolescents, adults, and older adults (2022) examined the efficacy

of psychological treatments, pharmacotherapy, and complementary and alternative medicine treatments.

- VNS may be an additional option for individuals who have not responded to at least four adequate trials of antidepressant treatment, including electroconvulsive therapy (ECT).
- VNS is approved for use in patients with treatment-resistant depression on the basis of its potential benefit with long-term treatment. There is no indication for the use of VNS in acute phase treatment of depression, as data showed no evidence for acute efficacy.

REGULATORY STATUS

The U.S. Food and Drug Administration (FDA) regulates vagus nerve stimulators as medical devices. All vagus nerve stimulators including related components require FDA approval before marketing and use in the United States to ensure they are safe and effective for human use. Refer to the FDA Medical Device website. Available from: https://www.fda.gov/medical-devices[accessed 2026 Jun 30]

The FDA lists the most serious type of medical device recalls as well as early alert communications about corrective actions being taken by companies that the FDA believes are likely to be the most serious type of recalls. Available from: Medical Device Recalls | FDA [accessed 2026 Jun 16]

The U.S. Food and Drug Administration (FDA) approved a vagus nerve stimulation device called the NeuroCybernetic Prosthesis system for treatment of seizures in July 1997. The data published in the medical literature are sufficient to conclude that vagal nerve stimulation improves health outcomes for individuals with partial onset seizures who are not candidates for surgery and whose seizures are refractory to other treatment. Studies have demonstrated that vagal nerve stimulation, as an adjunct to the optimal use of antiepileptic medications, in the treatment of medically refractory individuals with partial onset seizures reduces seizure frequency by approximately 25% after three months and, in most cases, the benefit treatment effect increases over time (up to a 50% reduction). Although FDA approval of this device is for individuals twelve years of age or older, studies on younger individuals have reported results similar to the adult trials, supporting the safety and efficacy of VNS in children with refractory seizures. Vagus nerve stimulation is carried out in centers experienced in the treatment of epilepsy.

The FDA approved Cyberonic's VNS Therapy System in July 2005 as an adjunctive long-term treatment of chronic or recurrent depression for individuals 18 years of age or older who are experiencing a major depressive episode and have not had an adequate response to at least four adequate antidepressant treatment regimens (medications and/or ECT). It is not intended as a first-line treatment, even for individuals with severe depression. In the D-01 depression case series, after 10-weeks of active VNS therapy, 30.5% of individuals had a 50% reduction in the depressive symptoms, based on the 28-item Hamilton Rating Scale for Depression (HRSD-28). In reports of longer-term outcomes, improvements in depressive symptoms continue out to one year, with 45% of patients having a 50% improvement in HRSD-28. These outcomes seem to stabilize out to two years, but there were substantial losses to follow-up (only 42 patients out of 60 available at two-year follow-up). The D-02 depression study was a double blind, randomized, placebo-controlled study (Rush et al 2005). Fifteen percent of patients in the active VNS group showed a 50% improvement on depressive

symptoms, whereas 10% of patients in the sham group showed a 50% improvement. A secondary outcome measurement, Inventory of Depressive Symptomology, self-rated (IDS-SR), showed a significant difference between the two groups, with 17.4% of patients in the VNS active group versus 7.5% of patients in the sham group demonstrating improvement. This randomized trial failed to achieve statistical significance with its primary endpoint. The available evidence does not permit conclusions about the usefulness of vagus nerve stimulation in the treatment of depression. Long-term data regarding the tolerability, as well as symptomatic and functional outcomes, of depressed patients receiving VNS are needed, to ascertain the effectiveness of this procedure for treating refractory depression.

In August 2021, the FDA approved a first-of-its-kind drug-free rehabilitation system intended to treat moderate to severe upper extremity motor deficits associated with chronic ischemic stroke using vagus nerve stimulation (VNS). The MicroTransponder Vivistim Paired VNS System (Vivistim System) is intended to be used to stimulate the vagus nerve during rehabilitation therapy in order to reduce upper extremity motor deficits and improve motor function in chronic ischemic stroke patients with moderate to severe arm impairment.

AspireSR Model 106 (Cyberonics) for Vagus Nerve Stimulation

The AspireSR Model 106 (Cyberonics, Inc.) received FDA premarket approval in February 2014. The newest modification to the vagus nerve stimulation (VNS) implant detects tachycardia heart rates, which may be associated with an impending seizure, and automatically delivers stimulation to the vagus nerve. Like its predecessors, the AspireSR can also deliver stimulation in the normal and magnet modes. However, when programmed for AutoStim mode, the AspireSR requires no patient interaction to trigger the delivery of electrical stimulation, as it is programmed to detect tachycardia and respond by delivering an extra automatic stimulation. The AutoStim mode should not be used in patients with significant arrhythmias being treated with pacemakers and/or an implantable defibrillator, beta-blockers, or any other treatment that may impact the intrinsic heart rate.

In November 2015, the FDA published a class 2 devices recall on all AspireSR Model 106 devices, due to a delay in the "Verify Heartbeat Detection" feature, which could decrease its battery life. In June 2017, Cyberonics recalled the M106 generators because of a manufacturing defect that could lower the longevity of the device. Instructions were sent to affected hospitals and physicians to monitor patients. In November 2017, Cyberonics recalled Model 3000 VNS Therapy Programmer, including models equipped with the Model 106 generator, due to a variety of problems that could lead to device failure or other complications, including delivery of more stimulation than intended or no stimulation. In January 2018, VNS Therapy Systems with the Model 106 generator were recalled because of a display warning issue.

Vagus Nerve Blocking Therapy

The FDA approved the Maestro Rechargeable System (Enteromedics) through the PMA process in January 2015. The device is indicated for use in adults aged 18 years and older who have a BMI of 40 to 45 kg/m2 or a BMI of 35 to 39.9 kg/m2 with one or more obesity-related comorbidities and have failed at least one supervised weight management program within the past five years. The Food and Drug Administration.[Internet]. Maestro Rechargeable System. Summary of Safety and

Effectiveness Data (SSED). Available from: https://www.accessdata.fda.gov/cdrh_docs/pdf13/P130019b.pdf [accessed 2026 Jun 16]

HCPCS Codes

Code	Description
C1767	Generator, neurostimulator (implantable), nonrechargeable
C1778	Lead, neurostimulator (implantable)
C1787	Patient programmer; neurostimulator
C1816	Receiver and/or transmitter, neurostimulator (implantable)
C1820	Generator, neurostimulator (implantable), with rechargeable battery and charging system
C1822	Generator, neurostimulator (implantable), high frequency with rechargeable battery and charging system
E0735 (E/I)	Noninvasive vagus nerve stimulator
L8679	Implantable neurostimulator pulse generator, any type
L8680	Implantable neurostimulator electrode, each
L8681	Patient programmer (external) for use with implantable programmable neurostimulator pulse generator, replacement only
L8682	Implantable neurostimulator radiofrequency receiver
L8683	Radiofrequency transmitter (external) for use with implantable neurostimulator radiofrequency receiver
L8685	Implantable neurostimulator pulse generator, single array, rechargeable, includes extension
L8686	Implantable neurostimulator pulse generator, single array, nonrechargeable, includes extension
L8687	Implantable neurostimulator pulse generator, dual array, rechargeable, includes extension
L8688	Implantable neurostimulator pulse generator, dual array, nonrechargeable, includes extension

Code	Description
L8689	External recharging system for battery (internal) for use with implantable neurostimulator, replacement only

ICD10 Codes

Code	Description
G40.001-G40.219	Localization-related (focal) (partial) idiopathic epilepsy and epileptic syndromes with seizures of localized onset (code range)
G40.301-G40.319	Generalized idiopathic epilepsy and epileptic syndromes (code range)
G40.A01-G40.A19	Absence epileptic syndrome (code range)
G40.B01-G40.B19	Juvenile myoclonic epilepsy, not intractable (code range)
G40.401-G40.419	Other generalized epilepsy and epileptic syndromes (code range)
G40.501-G40.509	Epileptic seizures related to external causes (code range)
G40.801-G40.919	Other epilepsy and recurrent seizures (code range)
G93.45	Developmental and epileptic encephalopathy
Investigational Codes:	
All other ICD10 diagnosis codes are considered investigational.

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: VENTRICULAR ASSIST DEVICE

POLICY EFFECTIVE DATE:	1/1/2026
Policy Control #:	1370/20.000473
Next Annual Review:	March, 2027

DISCLAIMER

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgement when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

PROCEDURE CODES

Percutaneous ventricular assist device: 33997
Total replacement heart system (artificial heart): 33927, 33928, 33929

DESCRIPTION

Ventricular assist devices (VADs) compensate for the diminished ability of the heart to pump blood into the circulatory system in individuals with acute or advanced chronic heart failure. Such implanted devices do not replace the heart, but rather work the patient's own heart to pump sufficient blood throughout the body. The VAD consists of a pump, control system, and an energy supply. Ventricular assist devices may be used to sustain patients awaiting heart transplantation, to facilitate cardiac recovery in patients suffering from reversible cardiac dysfunction, and to provide permanent circulatory support in patients with end-stage heart failure who are not candidates for transplantation.

POLICY NAME: VENTRICULAR ASSIST DEVICE

Payment Policies:

- Organ Transplant – Donor,1550/20.000207

POSITION STATEMENT

CDPHP considers use of an FDA-approved ventricular assist devices (VADs) medically necessary when used as labeled for any of the following indications:

Post-cardiotomy Setting

Post-cardiotomy is the period following open heart surgery. VADs are covered in the post-cardiotomy setting when used as a means of myocardial recovery support for patients who cannot be weaned from cardiopulmonary bypass.

Advanced Heart Failure

Ventricular assist devices (VADs) are covered if they are FDA approved for short-term (e.g., bridge-to-recovery and bridge-to-transplant) or long-term (e.g., destination therapy) mechanical circulatory support for heart failure patients who meet the following criteria:

- Have New York Heart Association (NYHA) Class IV heart failure; and
- Have a left ventricular ejection fraction (LVEF) ≤ 25%; and
- Are inotrope dependent

OR

- Have a Cardiac Index (CI) < 2.2 L/min/m2, while not on inotropes, and also meet one of the following:
    - Are on optimal medical management (OMM), based on current heart failure practice guidelines for at least 45 out of the last 60 days and are failing to respond; or
    - Have advanced heart failure for at least 14 days and are dependent on an intra-aortic balloon pump (IABP) or similar temporary mechanical circulatory support for at least seven days.

The implanting facility must also be part of the CDPHP designated specialty care network for ventricular assist device services.

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: VENTRICULAR ASSIST DEVICE

Percutaneous Ventricular Assist Devices

CDPHP considers the use of a percutaneous ventricular assist device (e.g., Impella 2.5, Impella 5.0, Impella CP), medically necessary in the following situations:

- Treatment of ongoing cardiogenic shock that occurs immediately following acute myocardial infarction or open-heart surgery as a result of isolated left ventricular failure that is not responsive to optimal medical management and conventional treatment measures that include volume loading, use of pressors and inotropes support with or without IABP.
- As an adjunct to post coronary intervention (PCI) in high-risk patients with unprotected left main or last-remaining-conduit PCI with LVEF < 35%, or with 3-vessel disease and LVEF < 30%.

Artificial Heart

CDPHP considers the use of an FDA approved total artificial heart (i.e., SynCardia™ t-TAH) medically necessary as a bridge to heart transplant in patients who meet all of the following criteria:

- At risk of imminent death from biventricular failure
- Have no other medical or surgical treatment options
- Ineligible for other ventricular support devices
- Approved for cardiac transplant and is currently on a transplant list
- Have sufficient space in the chest cavity to accommodate the device
- Is able to receive adequate anti-coagulation while on the total artificial heart
- Absence of irreversible organ dysfunction

POLICY CONSIDERATIONS

CDPHP will consider VADs used as a bridge to transplantation reasonable and necessary only when performed at facilities that are part of the CDPHP designated specialty care network for heart transplant or ventricular assist device transplant services.

EXCLUSIONS

The following exclusions apply:

- Use of a non-FDA approved ventricular assist device is considered investigational.
- Use of a ventricular assist device for indications other than those described in this policy.
- Use of a percutaneous ventricular assist device for indications other than those described in this policy.
- Total artificial hearts are considered investigational in all other circumstances including:
    - For use as destination therapy (permanent replacement of the failing heart).

CDPHP PRODUCT VARIATIONS

CHILD HEALTH PLUS	Subject to all terms and conditions noted above in the policy.

MEDICARE ADVANTAGE	Subject to all terms and conditions noted above in the policy with the following additions.
	
	Destination VAD implantation must be performed in a Medicare approved heart transplant facility that has demonstrated competency in performing the procedure as follows:
	• Facilities must be credentialed by an organization approved by the Centers for Medicare & Medicaid Services and in compliance with the following requirements:
	  • At least one physician with cardiothoracic surgery privileges and individual experience implanting at least 10 durable, intracorporeal, VADs (as bridge-to-transplant or destination therapy) over the course of the previous 36 months with activity in the last year; and
	  • At least one cardiologist trained in advance heart failure with clinical competence in medical and device-based management including VADs, and clinical competence in the management of patients before and after heart transplant.
	  • A VAD program coordinator, social worker, and palliative care specialist.
	The listing of CMS approved credentialing organizations/VAD destination facilities can be located at: https://www.cms.gov/Medicare/Medicare-General-Information/MedicareApprovedFacilitie/VAD-Destination-Therapy-Facilities.html

SELECT PLAN/HARP:	Subject to all terms and conditions noted above in the policy.

POLICY APPROVAL DATES

New:	03/12
Revised:	03/13, 01/14, 03/14, 03/15, 03/16, 05/17, 01/18, 05/18, 03/19, 01/21, 3/21, 3/23 3/26
Reviewed:	3/20, 3/22, 3/24, 3/25

POLICY HISTORY

This section is intended to provide only highlights of the policy changes. The policy should always be reviewed in its entirety to ensure a comprehensive understanding of coverage.

Effective Date	Update
1/1/26	Removed the following codes from the policy as HealthHelp will be reviewing the codes: 33975 33976 33977 33978

POLICY NAME: VENTRICULAR ASSIST DEVICE

	33979 33980 33981 33982 33983 33990 33991 33992 33993 33995
7/1/21 *No change to policy effective date	Under artificial hearts • For the bullet that states: o Have sufficient space in the chest cavity to accommodate the device- removed the body surface area (BSA) requirement as there are now artificial hearts that have different BSA requirements Under exclusions added: • Use of a percutaneous ventricular assist device for indications other than those described in this policy.
7/1/21	Added additional criteria for artificial hearts.
1/12/21	Revised title of policy. Added new code 33995 and 33997 To Procedure Codes section. Revised criteria for VADs for Advanced Heart Failure per updated Medicare NCD and removed references to retired Medicare NCD for Artificial Hearts.

CDPHP reserves the right to review this policy at any time and change it without notice.

Background

Complement hyperactivation, angiopathic thrombosis, and protein-losing enteropathy (CHAPLE) is an ultra-rare, potentially fatal autoimmune disorder. This disorder causes complement system overactivation, caused by mutations in the CD55 gene, leading to the complement system attacking the body's own cells (lack of control of the complement activity).

Decay Acceleration Factor [DAF or CD55] regulates compliment activation by dissociating subunit proteins for the bimolecular C3 convertases and the trimolecular C5 convertases, among other functions and is expressed on the membrane of blood cells and endothelial/epithelial cells of organs in contact with blood and lymph. Without the proper functioning of the DAF, however, complement activations may continue to the formation of membrane attack complexes (MACs), leading to inflammatory response and tissue damage.

The FDA reports there are fewer than 100 patients diagnosed worldwide.

Clinical presentations of CHAPLE disease include hypoproteinemia, hypogammaglobulinemia, bowel obstructions, enteritis, thrombosis, edema, lymphangiectasia, and increased infection risk (GI and thrombosis sequelae).

There are no FDA approved therapies to manage this ultra-rare condition, however Soliris (eculizumab) has been used off-label to treat this disease. Eculizumab therapy functions to block C5 activation (to produce C5a and C5b) which eliminates most harmful effects of caused by self-incurred injuries through formation of MACs.[7]

Veopoz was studied in a very small subject population with CHAPLE disease. Patients received a single loading dose of pozelimab 30mg/kg intravenously on day 1, followed by weight-based doses subcutaneously weekly. Ten patients ranging from 3 to 19 years of age (median of 8.5 years) were assessed for efficacy. The primary endpoint of the study was the proportion of patients with active disease at baseline achieving both normalization of serum albumin and clinical outcome improvement. Results from this study showed all 10 patients achieved normalization of serum albumin at 12 weeks and maintained serum albumin concentrations within the normal range through at least 72 weeks of treatment. The median time for serum albumin to reach at least 3.5g/dL was reported to be 15.5 days (95% CI, 8-28). Additionally, all participants did demonstrate a reduction in the number of hospitalizations and number of albumin transfusions over the first 48 weeks of treatment compared to the 48 weeks prior to initiation of therapy.

The most common adverse reactions to Veopoz are upper respiratory tract infections, fractures, hives, and alopecia. A Black Box Warning exists for life-threatening and fatal meningococcal infections that have occurred in patients treated with complement inhibitors and may become rapidly life-threatening or fatal if not recognized and treated early. Patients receiving Veopoz should complete or update meningococcal vaccination at least two weeks before treatment.

Summary

Effective Date of Policy:	9/10/2025
Indications	Treatment of adult and pediatric patients one year of age and older with CD55-deficient protein-losing enteropathy (PLE), also known as CHAPLE disease
ICD10 Diagnosis Codes	D84.1
Availability	*Injection: 400 mg/2 mL (200 mg/mL) in a single-dose vial*
Duration	Initial: Six months Continuation: 12 months
HCPCS Code	J9376

Required Criteria for Initial Approval		
All of the following conditions for the requested indication must be met in order to approve therapy:		
Specific Indication	**Inclusion Criteria**	**Recommended Dosing Regimen**

Treatment of adult and pediatric patients 1 year of age and older with CD55-deficient protein-losing enteropathy (PLE), also known as CHAPLE disease
(FDA approval)
ICD10: D84.1
	• Enrollee is at least one year of age
	• Must be prescribed by or in consultation with a hematologists, gastroenterologist or prescriber who specializes in the treatment of PLE/CHAPLE disease
	• Must have a diagnosis of CD55-deficient protein-losing enteropathy (PLE), also known as CHAPLE disease, confirmed by biallelic CD55 loss-of function mutation by genetic testing
	• Must have active disease defined as:
	  ○ a. Hypoalbuminemia ≤ 3.2 g/dL AND
	  ○ b. One of the following signs or symptoms attributable to PLE/CHAPLE disease within the previous 6 months:
	  ▪ i. Diarrhea
	  ▪ ii. Vomiting
	  ▪ iii. Abdominal pain
	  ▪ iv. Peripheral or facial edema
	  ▪ v. Infection with concomitant hypogammaglobulinemia
	  ▪ vi. New thromboembolic event
	• Enrollee will not be receiving concomitant complement therapy (i.e., Soliris/Bkemv/ Epysqli (eculizumab), Ultomiris (ravulizumab-cwvz))
	
	Veopoz will be considered investigational when used for all other off-label indications and will not be covered.
		• Day 1 (loading dose): Administer a single 30 mg/kg dose by intravenous infusion after dilution
		• Day 8 and thereafter (maintenance dosage): Inject 10 mg/kg as a subcutaneous injection once weekly starting on Day 8
		• The maintenance dosage may be increased to 12 mg/kg once weekly if there is inadequate clinical response **after at least three weekly doses (i.e., starting from Week 4)**
		• **The maximum maintenance dosage is 800 mg once weekly**

Continuation Criteria
• Requests will be reviewed per criteria every twelve months • Documentation of clinical benefit (such as improvement in clinical symptoms [e.g., abdominal pain, bowel movement frequency, facial or peripheral edema severity], increase or stabilization of albumin and IgG concentrations, increase in growth percentiles)

Considerations
• Prior authorization is obtained through the CDPHP pharmacy department.

Our medical policies are based on the assessment of evidence based, peer-reviewed literature, and professional guidelines. Eligibility for reimbursement is based upon the benefits set forth in the member's subscriber contract. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Vision therapy that includes orthoptics and occlusion therapy is considered **medically appropriate** for the treatment of amblyopia.

II. Vision therapy that includes prism adaptation is considered **medically appropriate** when utilized for acquired esotropia prior to surgical intervention.

III. Vision therapy is considered **medically appropriate** for the treatment of convergence insufficiency.

IV. Vision therapy using web-based and/or digital programming/therapeutics is considered **investigational** (e.g., Luminopia, RevitalVision, CureSight-CS100).

V. Vision therapy is considered **investigational** for **ALL** other indications including, but not limited to, the following:

   A. All other accommodative and vergence dysfunctions, (e.g., fusional vergence dysfunction, divergence excess, convergence excess, divergence insufficiency, vertical phorias, basic exophoria, basic esophoria, accommodative insufficiency, sustained accommodation, accommodative infacility, and spasm accommodation);

   B. Low vision;

   C. Myopia;

   D. Nystagmus;

   E. Presbyopia;

   F. Strabismus, including esotropia (with the exception of acquired esotropia as stated above) and exotropia; and

   G. Age-related macular degeneration.

   H. Learning disabilities; including attention deficit hyperactivity disorder (ADHD)

   I. Dyslexia

DESCRIPTION

Vision therapy (also known as visual therapy, visual training, vision training, or eye training) involves a range of treatment modalities that include the use of lenses, prisms, filters, optometric phototherapy (syntonics), occlusion therapy (eye patching), behavioral modalities, and eye exercises (orthoptics, pleoptics). The therapeutic goal of vision therapy is to correct or improve specific visual dysfunctions. Vision therapy is performed in an optometrist's or ophthalmologist's office one to two times weekly for a number of months, with additional home exercises done as reinforcement.

Luminopia is a software-only digital therapeutic designed to be used with commercially available Head-Mounted Displays (HMDs). Luminopia is indicated for improvement in visual acuity in amblyopia patients and is intended to be used as an adjunct to full-time refractive correction, such as glasses, which should also be worn under the HMD during Luminopia therapy. Their proprietary software uses a dual-action mechanism taking the content, modifying it in real-time, and presenting it differently to each eye to rebalance the input to the brain. The contrast of the stronger eye image is reduced to encourage the brain to pay more attention to the weaker eye and complementary masks remove parts of each eye's image, teaching the brain to combine input from both eyes.

RevitalVision is a perceptual learning vision training software program that aims to improve the brains visual processing and vision in amblyopic individuals. Training is done while the dominant eye is blurred with a semi-transparent white cover. By improving the brains visual processing to perform better, it compensates for some blurry images caused by small refractive error and allows patients to see better without correction.

CureSight-CS100 (NovaSight) is a digital eye tracking treatment using a special device and red-blue treatment glasses. The treatment is carried out while the child watches any streamed content of choice at home, under the remote supervision of an eye care provider and a dedicated Monitoring Center. By tracking the gaze position of both eyes in real-time, the CureSight system blurs the center of vision of the dominant eye and provides the amblyopic eye with a normal sharp image. This stimulates the visual system to use the information coming from the amblyopic eye to process the fine details, improving its acuity and developing stereoacuity as the eyes learn to work together. Indications for use include pediatric patients aged 4 to < 9 years with amblyopia associated with anisometropia and/or mild strabismus. CureSight is intended as an adjunct to full-time refractive correction (e.g., glasses). Available by prescription-only, for at-home use under supervision of an eye care provider.

SUPPORTIVE LITERATURE

Most studies evaluating the efficacy of vision therapy for visual disorders are small. In general, these studies are poorly designed, with significant methodological flaws, and the data derived from them

are relatively weak and inconclusive. There is some evidence to support the use of vision therapy that involves occlusion as a treatment for amblyopia (treatment success with patching are 72.3% -79%) and vision therapy that involves prism adaptation prior to surgery administered as a treatment for acquired esotropia (surgical success rates for prism adaption prior to surgery are 89% versus 72% for patients receiving no prism therapy). Large, well-designed studies comparing vision therapy with other treatment modalities, standardization of outcome measurements, and the criteria for defining patient selection are needed to adequately evaluate vision therapy for visual dysfunctions.

Hernández-Andrés (2025) published a randomized controlled trial comparing the results of three (3) treatments, two (2) combining patching with active therapy and one (1) with patching alone. Fifty-two amblyopic children (aged 4-12 years), were randomly assigned to three (3) monocular treatment groups: perceptual learning with a computer game designed to favor the medium-to-high spatial frequency-tuned achromatic mechanisms of parvocellular origin (n=17), vision therapy with a specific protocol and 2-h patching (n=17), and the third treatment group used 2-h patching only (n=18). Visual outcomes were analyzed after 3 months and compared with a control group (n = 36) of subjects with normal vision. Visual acuity (VA) and stereoacuity (STA) improved significantly after treatment for the three groups with the best results for patching plus vision therapy, followed by monocular perceptual learning, with patching only least effective. The authors concluded that this study showed visual acuity and STA improved with the two most active treatments, that is, vision therapy followed by perceptual learning. These results suggest that vision therapy should include monocular accommodative exercises, ocular motility, and central fixation exercises where the fovea is more active.

Singh et al (2021) published results of an RCT to assess and compare the effectiveness of home-based pencil push-up therapy (PPT) and office-based orthoptic therapy (OBOT) in 176 children and young adults with convergence insufficiency. Patients were randomized to 6 weeks of OBOT (3 times per week) or PPT (15 minutes per day). At study end, there was no difference between groups in near point of convergence or Convergence Insufficiency Symptom Survey scores, but there was a significantly greater improvement in positive fusional vergence with office-based therapy compared to home-based exercises ($p<.001$). Limitations of this study include lack of blinding, a wide range of patient ages, short duration compared to other studies, 20% to 30% loss to follow-up leading to a lack of power, and the study was conducted at a single center in India.

Verma et al (2025) published results from a one-year prospective, interventional, comparative study of the surgical outcomes of patients with acute acquired comitant esotropia (AACE) managed with and without pre-operative prism adaptation test (PAT). Forty patients with AACE were randomly divided into two groups by computerized randomization - those undergoing surgery after pre-operative PAT and those undergoing surgery without it. In the control group (Group C), patients underwent surgery based on the angle of deviation at distance measured by prism bar cover test (PBCT) and wearing full cycloplegic correction, while in test group (Group T), patients underwent surgery based on the preoperative prism-adapted angle at distance wearing prism power determined by PBCT and wearing full cycloplegic correction. The mean SD (standard deviation) of the PBCT for distance (measured in prism diopters - PD), PBCT for near (measured in prism diopters - PD) and stereopsis for near (measured in seconds of arc using Titmus Fly Test) at last follow-up visit (week

12) in the test versus control group were as follows: 1.70 ± 1.42 PD versus 4.75 ± 3.39 PD, 2.55 ± 1.82 PD versus 6.95 ± 3.35 PD and 74.90 ± 53.47 sec of arc versus 48.60 ± 31.97 sec of arc, respectively, which were statistically significant (p = <0.01, p = <0.01 and p = .03, respectively). The authors concluded that their study showed surgical outcomes in patients of AACE are better when surgical planning is done after performing pre-operative PAT as opposed to when surgery is planned without PAT. Better motor alignment (less under correction and over correction) and better sensory results in terms of improvement in stereopsis were observed.

Hofsli et al (2025) published results from an observational, retrospective study of individuals with symptomatic esophoria (SE) (that progresses into a manifest esotropia), comparing rates of repeated surgical interventions with or without PAT as a supplement to standard orthoptic evaluation. This study was conducted by reviewing records of patients who underwent surgery at the Department of Ophthalmology, Rigshospitalet, Glostrup, Denmark, from January 1, 2017, to August 31, 2023. Primary outcome was the need for repeated intervention either by reoperation or by postoperative adjustment of sutures. A total of 105 SE patients were included, with 61 in the non-PAT group and 44 in the PAT group. Repeated surgical interventions were less frequent in the PAT group (23%) compared to the non-PAT group (48%) (P 0.009). PAT resulted in an increase in median angles of deviation (AOD) at near and distance by 14PD and 16PD, respectively (p < .001 and p < .001). The authors concluded this study showed SE patients undergoing PAT had significantly lower rates of repeated surgical interventions and a significant increase in baseline AOD, compared to those who did not undergo PAT.

The use of digital programs (e.g., Luminopia, RevitalVision, CureSight-CS100) have been proposed for the treatment of amblyopia. Overall, the literature supporting its use consists of randomized trials with small sample sizes and short-term outcomes. Larger studies comparing digital programs to a relevant comparator with longer follow-ups are needed. The available evidence is insufficient to evaluate the effect of its use on health outcomes.

PROFESSIONAL GUIDELINE(S)

The American Academy of Pediatrics (AAP), American Association for Pediatric Ophthalmology and Strabismus (AAPOS), American Association of Certified Orthoptists (AACO) and American Academy of Ophthalmology (AAO) published a joint policy statement on learning disabilities, dyslexia, and vision (2009; reaffirmed 2014). They state:

- "Diagnostic and treatment approaches for dyslexia that lack scientific evidence of efficacy such as behavioral vision therapy, eye muscle exercises, or colored filters and lenses are not endorsed or recommended.
- Detailed review of the literature supporting vision therapy reveals that most of the information is poorly validated, because it relies on anecdotes, poorly designed studies, and poorly controlled or uncontrolled studies.
- There is currently no evidence that children who participate in vision therapy are more responsive to educational instruction than are children who do not participate."

The American Association for Pediatric Ophthalmology and Strabismus (AAPOS) describe vision therapy as an attempt to develop or improve visual skills and abilities; improve visual comfort, ease, and how well the eyes work; and change visual processing or understanding of visual information. (AAPOS 2023). A vision therapy program can consist of in-office and home eye exercises and may last for several months. Along with exercises, lenses, prisms, filters, patches, electronic targets, or balance boards may be used in vision therapy. They describe three (3) main types of vision therapy:

- Behavioral/perceptual vision therapy – eye exercises to improve visual processing and visual understanding.
- Vision therapy for prevention or treatment of myopia (nearsightedness).
- Orthoptic vision therapy - different type of eye exercises to improve binocular function (how well the two eyes work together). This type of eye exercise is taught in the office and done at home.

AAPOS states there is no evidence that vision therapy for learning disabilities, dyslexia or myopia, behavioral vision therapy or training glasses work to improve vision. They continue to state that orthoptics can be helpful in the treatment of eye movement problems that cause blurry vision, double vision, or headaches (like convergence insufficiency).

The American Academy of Ophthalmology (AAO) amblyopia preferred practice pattern (Cruz 2023) states:

- "Suitable treatment options for amblyopia include optical correction, patching, pharmacological treatment, optical treatment, Bangerter (translucent) filters, digital therapeutics, and managing the underlying cause of amblyopia.
- Most children who have moderate amblyopia (20/40 to 20/80) respond to initial treatment consisting of 2 hours of daily patching or weekend atropine."

The AAO esotropia and exotropia preferred practice pattern (Sprunger 2023) states treatment for esotropia includes the following:

- correction of refractive errors
- bifocal eyeglasses
- prism therapy
- extraocular muscle surgery:
- botulinum toxin injection
- other pharmacologic agents.

They go on to say in some patients with acquired esotropia less than 30 prism diopters who have diplopia, prism therapy may be beneficial in promoting binocular vision.

The American Optometric Association published optometric clinical practice guidelines for the care of the patient with amblyopia (2004). They explain the following treatment options:

- "Occlusion has been the cornerstone of treatment of amblyopia for over 200 years. The rationale for using occlusion is that occluding the better eye stimulates the amblyopic eye, decreasing inhibition by the better eye.
- Vision therapy refers to the total treatment program, which may include passive therapy options (e.g., spectacles, occlusion, pharmacologic agents) and active therapy. With such passive treatment options as optical correction and occlusion, the patient experiences a change in visual stimulation without any conscious effort. Active therapy is designed to improve visual performance by the patient's conscious involvement in a sequence of specific, controlled visual tasks or procedures that provide feedback about the patient's performance. When a reflexive response is achieved, it is anticipated that improved performance will transfer to other noncontrolled visual tasks, ultimately changing the underlying visual processing mechanism.
- Active vision therapy for amblyopia is designed to remediate deficiencies in four specific areas: eye movements and fixation, spatial perception, accommodative efficiency, and binocular function. The goal of vision therapy is remediation of these deficiencies, with subsequent equalization of monocular skills and, finally, integration of the amblyopic eye into binocular functioning.
- Active monocular and binocular amblyopia therapies, as opposed to passive management (e.g., occlusion), reduce the total treatment time needed to achieve the best visual acuity. Monocular therapy involves stimulation techniques that enhance amblyopic resolution and foster more normal eye movements, central fixation, and accommodation of the amblyopic eye. Because active binocular inhibition is one of the underlying etiologies of unilateral types of amblyopia, antisuppression procedures are performed under binocular conditions or in-instrument conditions simulating binocular conditions."

REGULATORY STATUS

CureSight-CS100 received FDA's 510(k) clearance for the CureSight-CS100 system (K221375) on September 29, 2022. More information is available from: https://www.accessdata.fda.gov/cdrh_docs/pdf22/K221375.pdf [accessed 2025 Sep 26].

Luminopia One received FDA's De Novo classification (DEN210005) on October 20, 2021. More information is available from: https://www.accessdata.fda.gov/cdrh_docs/pdf21/DEN210005.pdf [accessed 2025 Sep 26].

RevitalVision technology received FDA's 510(K) clearance August 31, 2001 (K012530), originally branded as the NeuroVision AA-1 system. More information is available from: https://www.accessdata.fda.gov/cdrh_docs/pdf/K012530.pdf [accessed 2025 Sep 26].

MEDICAL POLICY

Medical Policy Title	**Vitrectomy Chair/Face-down Positioning System**
Policy Number	**1.01.52**
Current Effective Date	**November 1, 2026**
Next Review Date	**April 2027**

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service. (Link to Product Disclaimer)

POLICY STATEMENT(S)

I. Use of a vitrectomy chair or face-down support system is considered **medically appropriate** following vitrectomy surgery, if a face-down position is required.

RELATED POLICIES

Not Applicable

POLICY GUIDELINE(S)

I. Benefits for a vitrectomy chair/face-down support system are provided through rental only.

DESCRIPTION

A vitrectomy is the surgical removal of the vitreous humor and is performed to clear blood and debris from the eye, to remove scar tissue, or to alleviate traction on the retina. At the completion of the surgery, gas or silicone oil may be injected into the eye, creating a bubble for retinal tamponade to keep the retina in place. As the retina is located in the back of the eye, recovering patients may be required to maintain a face-down position in order for the bubble to effectively apply pressure to the area, to enhance healing. The pressure allows the retina to re-bond with the eye wall, while new vitreous forms and replaces the bubble. Common indications for vitrectomy include macular hole repair, detached retina, vitreous hemorrhage, macular pucker, macular edema, diabetic retinopathy, and trauma.

A vitrectomy chair or face-down support system is designed for use by patients who have undergone vitrectomy surgery and thus assists with maintaining the face-down positioning requirement. Some patients may require the position for only a day, while others may have to maintain several hours daily of a face-down position for as long as three weeks.

SUPPORTIVE LITERATURE

A face-down vitrectomy system can assist in the maintenance of a face-down position, postoperatively, for those patients whose surgeon has recommended the device. Many patients are

more readily able to comply with the strict positioning requirements when utilizing the device. Some studies have demonstrated better outcomes in healing utilizing face-down positioning.

Hu Z, et al (2016) conducted a meta-analysis of four randomized control trials (RCTs) comprising 251 cases which concluded that no-face-down positioning had similar results to face-down positioning for holes smaller than 400 μm, but face-down positioning may be beneficial for holes larger than 400 μm.

Another meta-analysis (Ye 2019) of five randomized controlled trials composed of a total of 183 eyes in the face down positioning group (FDP) and 175 eyes in the non-face down positioning (nFDP) group which studied the closure rate of macular holes (MH) following surgery. Statistical meta-analysis revealed that the overall MH closure rate in the FDP group was significantly higher than that in the nFDP group (OR = 2.27, 95% CI: 1.02 to 5.05, P = 0.04). For MH sizes smaller than 400 μm, the subgroup meta-analysis indicated that the closure rate of the FDP group was not significantly higher than that of the nFDP group (OR = 1.32, 95% CI: 0.39 to 4.49, P = 0.66). However, when MH size was larger than 400 μm, there was a significantly higher closure rate in the FDP group (OR = 2.95, 95% CI: 1.10 to 7.94, P = 0.03). The authors concluded that the meta-analysis provides evidence that a face-down postoperative position seems to be unnecessary when MHs are smaller than 400 μm but may be highly recommended for MHs larger than 400 μm.

A Cochrane review (Cundy 2023) included eight randomized controlled trials (RCTs), comprised of 709 eyes (699 participants) total, in which postoperative face-down positioning was compared to no face-down positioning following surgery for macular holes. The primary outcome of interest was closure of the macular hole. The primary outcome of successful anatomical hole closure at one to six months following surgery was reported in 95 of every 100 eyes of participants advised to position face-down for at least three days after surgery, and in 85 of every 100 eyes of participants not advised to position face-down (RR 1.05, 95% CI 0.99 to 1.12, 709 eyes, 8 studies, I^2 = 44%). Amongst the 327 eyes of participants with macular holes of at least 400 μm, hole closure was noted in 94 of every 100 eyes of participants advised to position face-down, and in 84 of every 100 eyes of participants not advised to position face-down (RR 1.08, 95% CI 0.93 to 1.26, 5 studies, I^2 = 62%). Amongst the 129 eyes of participants with macular holes of less than 400 μm, hole closure was noted in 100 of every 100 eyes of participants advised to position face-down, and in 96 of every 100 eyes of participants not advised to position face-down (RR 1.03, CI 0.97 to 1.11, 4 studies, I^2 = 0%). The included studies were not all directly comparable due to differences in the surgical techniques used and the durations of postoperative positioning advised.

PROFESSIONAL GUIDELINE(S)

The American Academy of Ophthalmology (AAO) preferred practice pattern for idiopathic macular hole (2024) state in the early days of macular hole surgery, patients were instructed to maintain a face-down position for 10 to 14 days postoperatively to optimize macular hole closure. Postoperative prone positioning is uncomfortable for the patient, even though immobilization is not required. In some patients, positioning may be extremely difficult or even lead to pressure sores or neuropathy. Studies have reported excellent results using face-down positioning for 1 to 3 days. Longer positioning may be required for holes larger than 400 μm or those with inadequate tamponade.

Extended duration of face-down positioning minimizes the risk of cataract progression and provides some tamponade of the macular hole.

CENTERS FOR MEDICARE AND MEDICAID SERVICES (CMS)

A vitrectomy chair/face-down support system is not addressed in National or Regional Medicare

coverage determinations or policies.

PRODUCT DISCLAIMER

- Services are contract dependent; if a product does not cover a service, medical policy criteria do not apply.
- If a commercial product (including an Essential Plan or Child Health Plus product) covers a specific service, medical policy criteria apply to the benefit.
- If a Medicaid product covers a specific service, and there are no New York State Medicaid guidelines (eMedNY) criteria, medical policy criteria apply to the benefit.
- If a Medicare product covers a specific service, and there is no national or local Medicare coverage decision for the service, medical policy criteria apply to the benefit.

Disclaimer Notice

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgment when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

Background

Vyvgart is a first-in-class human immunoglobulin G1 (IgG1) antibody fragment that binds the neonatal Fc receptor (FcRn), keeping antibodies in circulation and preventing FcRn from recycling IgG back into the blood. This causes a reduction in overall levels of IgG, including the abnormal AChR antibodies that are present in most patients with gMG.

Generalized myasthenia gravis is a chronic autoimmune, neuromuscular disease that causes muscle weakness and fatigue. The muscle weakness presenting in MG is due to an antibody-mediated immunologic attack directed at proteins in the postsynaptic membrane of the neuromuscular junction. Myasthenia gravis has been associated with antibodies against 3 postsynaptic proteins: acetylcholine receptor (AChR), muscle-specific kinase (MuSK), and low-density lipoprotein receptor-related protein 4 (LRP4). AChR antibody–positive patients represent the vast majority of gMG patients. There are two classifications of MG: ocular and generalized. In the ocular form the weakness is limited to the eyelids and extraocular muscles whereas in generalized the weakness involves the ocular, limb, and the respiratory tract. Many patients suffer from bulbar weakness (impairment of lower cranial nerves). This results in difficulty chewing, swallowing, talking, and even holding the head up. The degree of muscle weakness can fluctuate and vary in severity from person to person; however, it will generally improve with rest and worsen with physical activity. Other precipitating factors include pregnancy, infection, surgery, and stress. There is no cure for gMG, with symptoms progressing and often reaching their worst after a few years of disease onset.

Treatment options are aimed as managing the disease as no cure is known. Goals are restoring muscle strength and reducing disease activity as well as preventing myasthenic crisis. Therapeutic options are:

1. Symptomatic therapy with acetylcholinesterase inhibitors (e.g., oral pyridostigmine) to increase acetylcholine at the neuromuscular junction
2. Chronic immunosuppressive therapies to manage immune dysregulation (e.g., glucocorticoids, nonsteroidal immunosuppressants)
3. Rapid immunomodulatory therapies (e.g., intravenous [IV] immunoglobulin [IVIG], plasma exchange) for patients with severe disease or those experiencing myasthenic crisis
4. Thymectomy (i.e., surgical removal of the thymus gland); usually reserved for patients with a thymoma (10%–15% of MG patients) or for those < 60 years of age without a thymoma with AChR antibodies (the thymus plays a role in the pathogenesis of MG in seropositive patients)

Initial therapy is oral pyridostigmine for mild to moderate disease, whereas more severe disease is treated with IVIG (myasthenic crisis) followed by immunosuppressive therapy (corticosteroids, azathioprine, mycophenolate mofetil, cyclosporine, tacrolimus). It is noted that individuals will very likely utilize more than one of these medications in combination with each other. Those that are eligible for a thymectomy typically continue their medications and see an improvement approximately one year after surgery. Unfortunately, between 10 and 30 percent of those with MG do not respond to conventional immunosuppressive therapy and will require treatment with other therapies such as off-label Rituximab, IVIG, Plasma Exchange, or Soliris.

The approval of Vyvgart was based on results from the Phase 3 ADAPT trial, which evaluated the drug's safety and efficacy in 167 patients with gMG. The trial met its primary endpoint, demonstrating that Vyvgart provided clinically meaningful improvements in symptom severity compared with placebo (with background gMG therapy) (67.7% versus 29.7%, respectively) as measured by the Myasthenia Gravis Activities of Daily Living score. The most frequently reported adverse effects in this trial included headache and nasopharyngitis.

Vyvgart Hytrulo received approval by the FDA in June 2024 for the treatment of adult patients with chronic inflammatory demyelinating polyneuropathy (CIDP) following the stage 3 ADHERE trial. Patients who were improved with the use of Vyvgart Hytrulo in the open-label phase of the trial (n = 221) entered a randomized, double-blind, placebo-controlled withdrawal period. The Vyvgart Hytrulo group has a 61% reduction in the risk of relapse compared to the placebo group based on the time to the first adjusted Inflammatory Neuropathy Cause and Treatment Disability Scale (INCAT) deterioration of ≥ 1 point.

Summary

Effective Date of Policy:	6/9/2026
Indications	Treatment of adult patients with generalized myasthenia gravis (gMG) Treatment of adults with chronic inflammatory demyelinating polyneuropathy (CIDP)

ICD10 Diagnosis Codes	G70.0, G61.81
HCPCS	Vyvgart: J9332 Vyvgart Hytrulo: J9334
Availability	*Vyvgart Injection: 400 mg in 20 mL (20 mg/mL) single-dose vial* *Vyvgart Hytrulo: 1,008mg-11,200 units/5.6mL solution for injection vials (per FDA prescribing information, administer by healthcare professional only) and 1000 mg-10,000 units per 5 mL in a prefilled syringe*
Duration	Six months

Required Criteria for Initial Approval

All of the following conditions for the requested indication must be met in order to approve therapy:

Indication	Inclusion Criteria	Recommended Dosing

Generalized Myasthenia Gravis
 	
(FDA approval)
 	
ICD10: G70.0
	• Enrollee is ≥ 18 years of age
	• Must be prescribed by or in consultation with a neurologist. If geographically available, it is also recommended for patients to have been evaluated by a neuromuscular specialist.
	• Documentation of a diagnosis of gMG that must have all of the following characteristics:
	  o One of the following clinical findings:
	  ▪ History of abnormal neuromuscular transmission test demonstrated by single-fiber electromyography (SFEMG) or repetitive nerve stimulation
	  ▪ Demonstrated improvement in MG signs on oral cholinesterase inhibitors, as assessed by neurologist
	• Myasthenia Gravis Foundation of America (MGFA) Clinical Classification Class II-IV
	  o Ocular MG is considered MGFA Class I, therefore not eligible to receive Vyvgart therapy
	• MG-Activities of Daily Living (MG-ADL) total score ≥ 5 with 50% of total score due to non-ocular symptoms at initiation of therapy
	• Must meet one of the following (A or B)
	  o A. Must have had serious side effects or drug failure to ONE of the following treatments for gMG (1 or 2).
	  ▪ 1. Corticosteroids for at least 3 months of treatment **OR**
	  ▪ 2. Non-steroidal immunosuppressive therapy (i.e., azathioprine, mycophenolate mofetil, cyclosporine) for at least 6 months of treatment **OR**
	  o B. Despite treatment with at least ONE immunosuppressant agent (i.e., corticosteroid, non-steroidal immunosuppressive therapy), the member required at least ONE treatment with plasma exchange, plasmapheresis, or intravenous immunoglobulin within the previous 12 months
	• For enrollee's who are not being treated with IVIG, enrollee has IgG levels of at least 6 g/L prior to starting therapy
	• Enrollee will not concurrently be receiving IVIG, Rituximab or Soliris (eculizumab)
	• Additional criteria for Vyvgart Hytrulo:
	  o Enrollee has adherently trialed at least 6 months of Vyvgart intravenous therapy with serious side effects or lack of clinical benefit, not expected to occur with Vyvgart Hytrulo
		Vyvgart:
		• 10 mg/kg administered as an intravenous infusion over one hour once weekly for four weeks (one cycle).
		• In patients weighing 120 kg or more, the recommended dose is 1200 mg per infusion.
		• Therapy cycles are repeated as needed depending on clinical response no sooner than eight weeks after initiation of the previous cycle.
		
		Vyvgart Hytrulo:
		• Vial is 1,008 mg / 11,200 units administered subcutaneously over approximately 30 to 90 seconds in cycles of once weekly injections for 4 weeks.
		• Administer subsequent treatment cycles based on clinical evaluation

Chronic Inflammatory demyelinating polyneuropathy
 	
ICD10: G61.81
	• Enrollee is ≥ 18 years of age
	• Therapy is being requested by a neurologist with expertise in the treatment of CIDP
	• Enrollee has a confirmed diagnosis of CIDP with supporting documentation (e.g., electrodiagnostic testing, clinical assessment, nerve biopsy)
	• Enrollee is refractory to treatment with at least 2 of the following:
	  o IVIG treatment lasting at least 3 months in duration
	  o Plasma exchange for at least one cycle (e.g., 4-6 exchanges over 8 to 10 days with subsequent exchange intervals dependent on response)
	  o Corticosteroid treatment (evidence-based regimen for CIDP)
	  o Rituximab (e.g., 375 mg/m^2 once weekly for 4 weeks per cycle) for at least one cycle
	• Must have documentation of baseline score on an objective scale to assess clinical response (e.g., Rankin, Modified Rankin, Medical Research Council (MRC), Inflammatory Rasch-built Overall Disability Scale (I-RODS), Inflammatory Neuropathy Cause and Treatment (INCAT) disability scale)
	• Additional criteria for Vyvgart Hytrulo:
	  o Enrollee has adherently trialed at least 6 months of Vyvgart intravenous therapy with serious side effects or lack of clinical benefit, not expected to occur with Vyvgart Hytrulo	

Exclusion Criteria

Therapy will not be authorized if any of the above Inclusion Criteria are not met OR any of the below noted Exclusion Criteria are met:

- Enrollee has Myasthenia Gravis Foundation of America Class I or V
- Enrollee has worsening muscle weakness secondary to concurrent infections or medications
- Enrollee has known seropositivity or who test positive for an active viral infection with:
  - Hepatitis B Virus (HBV) (except patients who are seropositive because of HBV vaccination)
  - Hepatitis C Virus (HCV)
  - Human Immunodeficiency Virus (HIV)
- Vyvgart/ Vyvgart Hytrulo will not be approved in combination with Uplizna, Soliris/Bkemv/ Epysqli, Ultomiris, Rystiggo, Imaavy, Zilbrysq, intravenous immunoglobulin (other than when used as rescue therapy), or rituximab-containing products as Vyvgart/ Vyvgart Hytrulo has not been studied in combination with these therapies.

Continuation Criteria

- Requests will be reviewed per criteria every six months.
- Enrollees should be assessed by provider after the first two cycles of Vyvgart to assess for disease response. Continuation of therapy will be authorized if disease response occurs defined as at least a two-point improvement in the MG-ADL score from the members pre-treatment baseline.

Considerations

- Prior authorization is obtained through the CDPHP pharmacy department.
- Because Vyvgart causes transient reduction in IgG levels, immunization with live-attenuated or live vaccines is not recommended during treatment with Vyvgart. Evaluate the need to administer age-appropriate vaccines according to immunization guidelines before initiation of a new treatment cycle with Vyvgart.
- Delay administration of Vyvgart to patients with an active infection. Monitor for signs and symptoms of infection in patients treated with Vyvgart.
- Quantity limit for Vyvgart Hytrulo PFS: 4 syringes (20 mL) per 28 days
- Vyvgart and Vyvgart Hytrulo vials will be covered under the medical benefit as these are intended to be administered by a healthcare provider.

Myasthenia Gravis Foundation of America Clinical Classification

Class	Description
Class I	Any ocular muscle weakness; may have weakness of eye closure. All other muscle strength is normal.
Class II	Mild weakness affecting muscles other than ocular muscles; may also have ocular muscle weakness of any severity.
Class III	Moderate weakness affecting muscles other than ocular muscles; may also have ocular muscle weakness of any severity.
Class IV	Severe weakness affecting muscles other than ocular muscles; may also have ocular muscle weakness of any severity.
Class V	Defined as intubation, with or without mechanical ventilation, except when employed during routine postoperative management.

GOVERNMENT PROGRAMS

CHILD HEALTH PLUS:	Subject to all terms and conditions noted in above application.
MEDICARE CHOICES:	Subject to all terms and conditions noted in above application.
SELECT/HARP PLAN:	Subject to all terms and conditions noted in above application. Vyvgart Hytrulo PFS: Effective April 1, 2023, the pharmacy benefit for Medicaid is administered by NYRx, the Medicaid Pharmacy Program.

CDPHP Pharmacy Services 6/9/2026

New: 2/2022

Revised	Reviewed
4/22, 4/23, 9/23, 9/24, 9/25	

Revision Date	Changes Made
4/2022	Removed Inclusion Criteria: History of positive anticholinesterase test (e.g., edrophonium chloride test) Updated wording of Inclusion Criteria with the addition of the **bolded** text: Enrollee has had an adequate trial **with clinically documented therapeutic failure** of at least one of the following options for the management of gMG: IVIG or Plasmapheresis.
4/2023	Updated IgG level to be applicable for enrollees who are not receiving IVIG therapy.
9/2023	Changed policy name from Vyvgart (efgartigimod) to Vyvgart and Vyvgart Hytrulo; added Vyvgart Hytrulo to policy.
9/2024	Added criteria for CIDP indication and included criteria requiring 6-month trial of Vyvgart before Vyvgart Hytrulo would be covered
9/2025	Added Vyvgart Hytrulo prefilled syringe to policy. Quantity limit for Vyvgart Hytrulo PFS: 4 syringes (20 mL) per 28 days.
6/2026	Removed positive serologic test of AChR antibodies for gMG Reworded medication trial for gMG

PROCEDURE CODES

A9282

DESCRIPTIONS

Wigs/cranial prostheses and toupees are manufactured coverings of natural or synthetic hair for the head.

POSITION STATEMENT

CDPHP administers benefits for a medically necessary wig/cranial prosthesis or toupee when there is severe hair loss due to injury or disease or as a side effect of the treatment of a disease. Severe hair loss due to injury, disease and/or side effect of treatment of a disease includes:

- Alopecia areata affecting a significant portion of the scalp and expected to be chronic in nature (lasting a year or more)
- Alopecia totalis
- Alopecia universalis
- Chemo or radiation therapy
- Congenital baldness
- Severe burns - 2nd degree full thickness and 3rd degree burns with resulting permanent alopecia

Capital District Physicians' Health Plan, Inc.
CDPHP Universal Benefits,® Inc.
Capital District Physicians' Healthcare Network, Inc.

(Collectively referred to within this policy as "CDPHP®")

POLICY NAME: WIGS/CRANIAL PROSTHESES &TOUPEES

EXCLUSIONS

Duplicate wigs for convenience purposes.

Billing of code D5924 (cranial prosthesis) is not an appropriate code for purposes of this policy as this is a specific dental procedure designed to restore craniofacial structures.

Wigs/cranial prostheses and toupees are not considered to be medically necessary if balding or hair loss is due to any of the following conditions:

- Androgenetic alopecia (male/female pattern baldness)
- Natural aging process
- Pregnancy or postpartum alopecia
- Premature balding at a young age

CDPHP PRODUCT VARIATIONS

CHILD HEALTH PLUS:	Subject to all terms and conditions noted above in the policy.
MEDICARE ADVANTAGE:	Subject to all terms and conditions noted above in the policy.
SELECT PLAN/HARP:	Subject to all terms and conditions noted above in the policy.

Background

Acid sphingomyelinase deficiency (ASMD) is a rare, autosomal recessive, progressive genetic disorder that results from a deficiency of the enzyme acid sphingomyelinase, which is required to break down (metabolize) a fatty substance (lipid) called sphingomyelin. As a result, sphingomyelin and other substances accumulate around the body tissues. ASMD can be considered as a spectrum of disease, as it is variable in symptoms, severity, and age of onset. Niemann-Pick disease Type A (NPD Type A) represents a severe end of this spectrum (fatal neurodegenerative disorder presenting in infancy) and conversely a mild representation includes either no or minimal neurological symptoms with survival into adulthood (Niemann-Pick disease Type B, NPD Type B). Many cases of ASMD fall between the two aforementioned extremes and are referred to as types A/B disease (intermediate disease). Some information suggests that mild to intermediate cases of disease may be considered Type B, even with neurological findings.

NPD Type A and B are due to mutations in the SMPD1 gene, which causes a deficiency of the Acid Sphingomyelinase (ASM) enzyme.

According to the National Organization for Rare Disorders, ASMD affects males and females in equal numbers with the exact incidence and prevalence of the disorder unknown. It has been estimated at 1 in 250,000 individuals in the general population are affected, however because some cases go misdiagnosed or undiagnosed, determining the true frequency of ASMD in the general population is difficult.

Diagnosis involves determining whether the ASM activity is reduced or absent. Peripheral blood leukocytes or cultured skin fibroblasts are examined to assess residual ASM activity, where a confirmation is achieved if a sample demonstrates < 10% that of a control sample. Molecular testing is available in specialized laboratories and can detect mutations in the SMPD1 gene. The diagnosis also relies upon clinical documentation of symptoms and laboratory abnormalities, although the condition is heterogeneous in extent and systems affected.

Treatment is largely supportive, attempting to manage the various bodily systems involved in the disease. Xenpozyme (olipudase alfa) is the first FDA approved medication (enzyme replacement therapy) to treat symptoms of ASMD not related to the central nervous system.

Given that Xenpozyme is not expected to cross the blood-brain barrier or modulate the CNS manifestations of ASMD, it was only studied in patients with ASMD type B or type A/B. The neurologic manifestations of ASMD type A are rapidly progressive and fatal, and Xenpozyme has not been studied in these patients.

Replacement of the ASM enzyme with the genetically engineered, recombinant form helps reduce sphingomyelin accumulation in the liver, spleen, and lungs. Xenpozyme is an intravenous infusion given every two weeks that has been studied in three clinical trials (ASCEND, NCT02004691, ASCEND-Peds, NCT02292654, and a long-term trial, NCT02004704). ASCEND evaluated the efficacy and safety of Xenpozyme in 31 adult patients with ASMD type A/B or type B who were randomized to receive Xenpozyme or placebo for 52 weeks with an extension treatment following for up to four years. ASCEND- Peds evaluated eight pediatric patients under 12 years of age with ASMD type A/B or type B. The primary endpoints were assessed at week 52 and included percent predicted diffusing capacity of the lungs for carbon monoxide (DLco), Spleen volume, liver volume, and platelet count. Improvements were seen in all assessed endpoints, which reached statistical significance (week 52), and this benefit was appreciated at week 104, as well as those who crossed over into active treatment at week 52. From a safety perspective, this agent carries a Black Box Warning for severe hypersensitivity reactions so it must be administrated where appropriate measures are readily available. Additionally, the most common adverse effects are headache, cough, diarrhea, hypotension, and ocular hyperemia.

Summary

Effective Date of Policy:	12/3/2025
Indications	Treatment of non–central nervous system manifestations of acid sphingomyelinase deficiency (ASMD) in adult and pediatric patients
ICD10 Diagnosis Codes	E75.249
Availability	*For injection: 4 or 20 mg of olipudase alfa-rpcp as a lyophilized powder in a single-dose vial for reconstitution*
Duration	Initial: 12 months Continuation: 12 months

Required Criteria for Initial Approval		
All of the following conditions for the requested indication must be met in order to approve therapy:		
Specific Indication	**Inclusion Criteria**	**Recommended Dosing Regimen**

Treatment of non–central nervous system manifestations of acid sphingomyelinase deficiency (ASMD) in adult and pediatric patients
 	
(FDA approval)
ICD10: E75.249
	• Therapy must be prescribed by or in consultation with a physician knowledgeable in the treatment of acid sphingomyelinase deficiency (ASMD)
	• Enrollee has a diagnosis of Type B or A/B ASMD with non-central nervous system (non-CNS) manifestations AND
	  o a. Must have documented deficiency, defined as < 10% enzyme compared to controls, of acid sphingomyelinase as measured in peripheral leukocytes, cultured fibroblasts, or lymphocytes OR
	  o b. Molecular genetic testing identifying a mutation in the SMPD1 gene
	• Enrollee does not have type A ASMD (also known as Niemann-Pick disease type A)
	• Baseline documentation of at least one of the following parameters will be required in order to verify clinical benefit upon recertification:
	  o Percent predicted diffusion capacity of the lungs for carbon monoxide (DLco).
	  ▪ i. Note: considerations will be granted for other age-appropriate lung function tests in pediatric patients unable to perform this test
	  o Spleen volume
	  o Liver volume
	  o Platelet count
	  o Linear growth progression (as measured by height Z-score) (only applicable to pediatric patients < 18 years of age)
	  o Lyso-sphingomyelin levels
		• Adults: Recommended starting dose is 0.1 mg/kg administered as an intravenous infusion.
		• Pediatrics: Recommended starting dose is 0.03 mg/kg administered as an intravenous infusion.
		• See Full Prescribing Information for the recommended dose escalation and maintenance dosage, dosage modifications to reduce the risk of adverse reactions, and preparation and administration instructions.
		• Xenpozyme is administered via intravenous infusion every 2 weeks

Continuation Criteria

- Requests will be reviewed per criteria every 12 months
- Documentation of improvement from baseline in at least one of the following:
  - Percent predicted diffusion capacity of the lungs for carbon monoxide (DLco).
    - i. Note: considerations will be granted for other age-appropriate lung function tests in pediatric patients unable to perform this test
  - Spleen volume
  - Liver volume
  - Platelet count
  - Linear growth progression (as measured by height Z-score) (only applicable to pediatric patients < 18 years of age)
  - Lyso-sphingomyelin levels

Considerations

- Prior authorization is obtained through the CDPHP pharmacy department.

- Xenpoxyme therapy carries a Black Box Warning for severe hypersensitivity reactions including anaphylaxis and that appropriate medical support measures, including cardiopulmonary resuscitation equipment, should be readily available. If a severe hypersensitivity reaction occurs, XENPOZYME should be discontinued immediately, and appropriate medical treatment should be initiated.
- Risk of fetal malformations during dosage initiation or escalation in pregnancy: Xenpozyme carries a pregnancy warning at any time during therapy. Use is not recommended as it may lead to elevated sphingomyelin metabolite levels that may increase the risk of fetal malformations. Advise females of reproductive potential to use effective contraception during treatment and for 14 days after the last dose if therapy is discontinued.

Policy/Procedure Name: Xiaflex (collagenase clostridium histolyticum) **Control Number: 1350/20.000574**

Disclaimer Notice

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgment when deciding the most appropriate care to enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

Background

Fibroproliferative disorders, characterized by excessive collagen deposits, can affect the musculoskeletal system, causing pain, limiting joint range of motion, and negatively impacting quality of life. Examples of these fibrotic tissue disorders include Dupuytren's contracture, adhesive capsulitis, and Peyronie's disease.

Collagenases, enzymes that digest native collagen and lead to the disruption of contracted cords, are being investigated as a non-surgical treatment for fibroproliferative disorders. Injection of collagenase clostridium histolyticum, a bacterial collagenase, is intended to provide a non-operative treatment option and is usually an office-based procedure.

Xiaflex (collagenase clostridium histolyticum, CCH) is FDA-approved for the treatment of Dupuytren's contracture with a palpable cord. The FDA labeling for Xiaflex states that up to three injections at four-week intervals may be given into a palpable Dupuytren's cord with a contracture of a metacarpophalangeal (MP) joint or a proximal interphalangeal (PIP) joint. This should be followed by manual manipulation of the affected joint to attempt rupture of the cord.

Additionally, Xiaflex has been FDA-approved for treatment of men with Peyronie's disease who have a penile curvature of at least 30 degrees. The dose of Xiaflex is 0.58 mg per injection, administered into a Peyronie's plaque. Up to eight injections (four treatment cycles) may be administered in the course of treatment. Also, a penile modeling procedure is recommended after every treatment cycle of two injections, in an effort to further disrupt the plaque. Expert opinion defines "functionally straight" as penile curvature less than or equal to 20 degrees.

In a prospective cohort study by Wymer and colleagues (2018), 115 patients with Peyronie's disease who completed at least two CCH cycles were analyzed for improvement in penile curvature, to assess for characteristics predictive of treatment success. Thirty-four of the 115 men included were found to have calcification. Patients with calcified plaque were more likely to have dorsal curvature and severe erectile dysfunction. Patients with noncalcified plaque and curvature of at least 60 degrees had the greatest improvement in curvature (defined as improvement in curvature greater than 20%). The authors concluded that calcification is one of the strongest predictors for CCH failure and that men with baseline curvature greater than 60 degrees are approximately 2.5 times more likely to experience a 20% or more improvement, compared to lesser curvatures.

Summary

HCPCS Code	J0775
Effective Date of Policy:	2/12/2026

Required Criteria for Initial Approval

Dupuytren's Contracture

1. Must be 18 years of age or older
2. Must be used for the treatment of Dupuytren's contracture in either the metacarpophalangeal (MCP) or proximal interphalangeal (PIP) joint when there is a palpable palmar cord.
3. Must have documentation that the contracture is at least 20 degrees prior to initiating Xiaflex therapy
4. Provider must attest to all of the following:
    a. The provider is experienced in
        i. Injection procedures of the hand
        ii. Treatment of patients with Dupuytren's contracture

   b. The provider has completed the necessary training to administer Xiaflex
   c. The provider and health care site are enrolled in the Xiaflex Managed Distribution Program for Dupuytren's contracture
5. The provider must specify the location of the cord being treated on the hand; indicating the hand, finger(s), and joint(s) affected
6. The dose of Xiaflex is 0.58 mg per injection into a palpable cord with a contracture of a MP joint or PIP joint
   a. Each vial of Xiaflex (supplied as 0.9 mg) and sterile diluent should only be used for a single injection
   b. Approximately 24 to 72 hours after injection, a finger extension procedure should be performed if a contracture persists to facilitate cord disruption
   c. If two joints on the same hand are to be treated during a treatment visit, separate vials and syringes should be used for each reconstitution and injection
7. Xiaflex injection is administered at four-week intervals for a total of 3 injections per cord/joint
   a. Xiaflex will not be authorized for retreatment beyond a total of 3 injections per cord/joint
8. If requesting two injections (two vials) in the same hand for a single treatment visit, one of the following must be met:
   a. The patient has two palpable cords affecting two joints on the same hand **OR**
   b. The patient has one palpable cord affecting two joints in the same finger
9. Approval duration as follows:
   a. For all **non-Managed Medicaid/HARP** lines of business: 6 months (for a total of 3 injections per cord/joint), to allow adequate time to complete treatment.
   b. For **Managed Medicaid/HARP**: 4 weeks **(limited to a maximum of 2 injections in the same hand for a single treatment visit as outlined in criterion #8)**
10. **Managed Medicaid/HARP ONLY**: Per New York State Department of Health Requirements, requests for Xiaflex require eligibility verification via EDVS system (13 years of age and older).

Peyronie's Disease

1. Must be 18 years of age or older
2. Must have a diagnosis of Peyronie's disease
3. Must have stable disease, defined by no change in symptoms (e.g., penile curvature and pain) for at least three months
4. Must have the presence of a palpable plaque at the site of maximum curvature
5. Must have documentation at the start of therapy of a curvature deformity between 30 and 90 degrees that causes a functional deficit (e.g., an inability to engage in sexual intercourse, sexual intercourse is painful for either partner, or penile pain) not attributable to other causes
6. Provider must attest that Xiaflex will be used in combination with a penile modeling procedure
7. Provider must attest that both of the following are met:
   a. The provider has experience in the treatment of male urological diseases
   b. The provider and health care site are certified through the Xiaflex REMS Program
8. The dose of Xiaflex is 0.58 mg (supplied as a 0.9 mg vial) per injection administered into a Peyronie's plaque. If more than one plaque is present, inject into the plaque causing the curvature deformity. A treatment course consists of a maximum of 4 treatment cycles. Each treatment cycle consists of two Xiaflex injection and one penile modeling procedure. The second Xiaflex injection procedure is performed 1 to 3 days after the first. The penile modeling procedure is performed 1 to 3 days after the second injection of the treatment cycle. The interval between treatment cycles is approximately 6 weeks. The treatment course, therefore, consists of a maximum of 8 injection procedures and 4 modeling procedures (four treatment cycles).

9. Xiaflex will be authorized for a maximum of four treatment cycles (two Xiaflex injection procedures and one penile modeling procedure per cycle), each separated by six weeks. Xiaflex will not be authorized beyond four treatment cycles (8 injections) per plaque.
10. Approval duration will be 12 months (for a total of 8 injections) to allow adequate time to complete treatment
11. Retreatment with Xiaflex will not be authorized when the penis is functionally straight (i.e., the curvature deformity is less than or equal to 20 degrees) after the first, second or third treatment cycle, or if further treatment is not clinically indicated.
12. **Managed Medicaid/HARP ONLY: The use of Xiaflex for the treatment of Peyronie's disease is not a covered benefit.**

Considerations

- Prior authorization is obtained through the CDPHP pharmacy department

Background

Asthma

Xolair (omalizumab) and Omlyclo (omalizumab-igec) are indicated for moderate to severe persistent asthma in adults and pediatric patients 6 years of age and older with a positive skin test or in vitro reactivity to a perennial aeroallergen and symptoms that are inadequately controlled with inhaled corticosteroids.

Asthma is a heterogeneous syndrome that might be better described as a constellation of phenotypes, each with distinct cellular and molecular mechanisms, rather than as a singular disease. One of these phenotypes is allergic asthma, which is associated with allergies to allergens such as pollen or dust mites. Chronic airway inflammation results in symptoms that include wheezing, shortness of breath, chest tightness, and cough.

Immunoglobulin E (IgE) plays a central role in the pathogenesis of allergic asthma. IgE activation of mast cells, and basophils causes the release of inflammatory mediators such as histamine, prostaglandins, cysteinyl-leukotrienes, and cytokines. Xolair (omalizumab) and Omlyclo (omalizumab-igec) are recombinant humanized monoclonal antibodies that inhibit the binding of IgE to the IgE receptors on the surface of mast cells, basophils, and dendritic cells. This results in receptor down-regulation on these cells and leads to a reduction in blood/tissue eosinophils and other inflammatory mediators.

Chronic Spontaneious Urticaria (CSU)

Xolair (omalizumab) and Omlyclo (omalizumab-igec) are indicated for chronic spontaneous urticaria (CSU) in adults and adolescents 12 years of age and older who remain symptomatic despite H1 antihistamine treatment.

Chronic spontaneous urticaria is defined by the presence of wheals (hives), angioedema (swelling), or both, most days of the week, for a duration of 6 weeks or longer. The hives may appear at any age, can occur anywhere on the body, and vary in size. They are typically itchy, raised, and appear as reddish areas on the skin. Angioedema may be painful and usually occurs in the face, throat, hands, and feet, though it can occur in other areas of the body as well. Usually, the cause of chronic urticaria cannot be identified.

Xolair (omalizumab) and Omlyclo (omalizumab-igec) are recombinant humanized monoclonal antibodies that binds to IgE and lowers free IgE levels, resulting in receptor down-regulation on cells. It is unknown how this mechanism improves symptoms in CIU.

Chronic Rhinosinusitis with Nasal Polyps (CRSwNP)

Xolair (omalizumab) and Omlyclo (omalizumab-igec) are indicated for chronic rhinosinusitis with nasal polyps (CRSwNP) in adult patients 18 years of age and older with inadequate response to nasal corticosteroids, as add-on maintenance treatment.

CRSwNP is a subtype of chronic rhinosinusitis (CRS). It is a heterogeneous chronic inflammatory disease of the nasal lining and sinuses, resulting in the development of noncancerous soft tissue growth (polyps) in the sino-nasal cavity. Symptoms include loss of smell, nasal congestion, and nasal drainage. Most patients with CRSwNP show evidence of type 2 inflammation. Nasal polyp tissue is characterized by local eosinophil inflammation in a large majority of patients with this condition. Despite optimized treatment, nasal polyps have a high rate of recurrence.

Xolair (omalizumab) and Omlyclo (omalizumab-igec) are recombinant humanized monoclonal antibodies that inhibits the binding of IgE to the IgE receptors on the surface of mast cells, basophils, and dendritic cells. This results in receptor down-regulation on these cells and leads to a reduction in blood/tissue eosinophils and other inflammatory mediators.

Food Allergies

Xolair (omalizumab) and Omlyclo (omalizumab-igec) are indicated for IgE-mediated food allergy in adult and pediatric patients aged 1 year and older for the reduction of allergic reactions (Type I), including anaphylaxis, that may occur with accidental exposure to one or more foods. To be used in conjunction with food allergen avoidance.

IgE-mediated food allergic reactions are rapid in onset, typically beginning within minutes to two hours from the time of ingestion. Most patients react to one or two specific foods/food groups, although an increasing number of patients react to multiple foods.

Xolair and Omlyclo are recombinant humanized monoclonal antibodies that inhibit the binding of IgE to the high-affinity on the surface of mast cells, basophils, and dendritic cells, which down-regulates the IgE receptors on these cells and reduces allergic reactions.

Summary	
Effective date	9/25/2026
Indications	Moderate to severe persistent allergic asthma, chronic idiopathic urticaria (CIU), nasal polyps, IgE-mediated food allergies
ICD10 diagnosis codes	J45, L50, J33.9, Z91 (select subcodes for specific allergens)
Availability	Xolair: 75 mg/0.5 mL, 150 mg/mL, and 300/2mL solution in a single-dose prefilled syringe and autoinjector; 150 mg lyophilized powder in a single-dose vial for reconstitution Omlyclo: 75 mg/0.5 mL, 150 mg/mL, and 300/2mL solution in a single-dose prefilled syringe
Limitations	Not indicated for other allergic conditions, other forms of urticaria, acute bronchospasm, or status asthmaticus
HCPCS	Xolair: J2357 Omlyclo: Q5154
Duration	Initial: Six (6) months Continuation: Two (2) years

Required Criteria for Initial Approval

All of the following conditions for the requested indication must be met in order to approve Xolair (omalizumab) or Omlyclo (omalizumab-igec).

Indication	Criteria
Severe persistent allergic asthma (FDA approval) ICD10: J45	1. Must be at least 6 years of age 2. Must be followed by, and drug ordered by a pulmonologist, allergist, or immunologist 3. Must have a diagnosis of moderate to severe persistent asthma 4. Must be a non-smoker defined as someone who has not smoked in the past 6 months 5. Must have baseline IgE levels between 30 and 700 IU/mL Coverage for IgE levels outside of this range will be considered as follows: a. Members with a baseline IgE level between 700 and 1300 IU/mL will be considered for Xolair therapy if all other criteria is met as long as the dose required based on IgE and body weight is not > 750 mg per month OR b. Member with baseline IgE level below 30 IU/mL will not be considered for coverage as there is not enough free IgE with which to bind for the drug to exert its effect 6. Must have at least one perennial aeroallergen (examples: dust mites, pet dander, cockroach) 7. Must have experienced two or more asthma exacerbations within the preceding 12 months that required medical management 8. Must have well documented use of high-dose inhaled corticosteroids for at least 3 months, be compliant with existing therapy, and have followed GINA guidelines for asthma treatment including adequate trial of a high-dose inhaled steroid in combination with a long-acting beta agonist 9. Initial approval will be for 6 months. Continuation can be approved for 2 years and will require objective assessment of response to therapy with Xolair or Omlyclo as well as compliance with the inhaled corticosteroid and controller medication.
Chronic Spontenaeous urticaria (FDA approval) ICD10: L50	1. The request is obtained by or in consultation with an allergist, immunologist, or dermatologist 2. Must be at least 12 years of age 3. Must have a minimum six-week history of urticaria characterized by wheals (hives), angioedema, or both despite adequate trials of: a. A second generation H1-antihistamine at standard dosing AND a second generation H1-antihistamine trialed at 2-4 times the standard dose

	i. This criterion may be satisfied by using either the same second generation H1-antihistaime at standard dosing and 2-4 times standard dosing OR using two different second generation H1-antihistamines with at least one agent being at 2-4 times standard dosing 4. Initial approval will be for 6 months 5. Continuation of therapy can be approved for 2 years and will require documentation that the patient has responded to or continues to benefit from therapy
Chronic Rhinosinusitis with Nasal Polyps (CRSwNP) (FDA approval) ICD10: J32.9 (chronic sinusitis), J33.9 (nasal polyp, unspecified)	1. The prior authorization is requested by or in consultation with an allergist, immunologist, or otolaryngologist 2. Must be at least 18 years of age 3. Must have a diagnosis of chronic rhinosinusitis with nasal polyps (CRSwNP) a. Chronic is defined as having lasted for at least 12 weeks AND b. Must currently have nasal polyposis, confirmed by evidence (such as direct examination, nasal endoscopy, imaging studies (such as a sinus CT scan)) 4. Must have a documented inadequate response despite at least 3 months of compliant use of mometasone nasal spray at a dose of 2 sprays in each nostril twice daily 5. Must have a documented inadequate response despite at least 3 months of compliant use of Xhance nasal spray at a dose of 2 sprays in each nostril twice daily. 6. Must have had either: a. Prior nasal surgery **OR** b. Prior treatment with a course of systemic corticosteroids 7. Must be used in combination with an intranasal corticosteroid a. Xolair as monotherapy for this indication will not be authorized as it is only FDA approved as an add-on maintenance treatment for this indication 8. Must have baseline IgE level between 30 and 1500 IU/mL a. Dosing is based on IgE level and body weight b. Members with a baseline IgE level above 1500 IU/mL will be considered for Xolair or Omlyclo therapy if all other criteria are met and as long as the dose required based on IgE and body weight does not exceed 600 mg every 2 weeks 9. Initial approval will be granted for 6 months. Continuations can be approved for 2 years and will require documentation of continued use of an intranasal corticosteroid and clinical benefit from Xolair or Omlyclo use
Mitigation of IgE mediated allergic food reactions, including anaphylaxis, that may occur with accidental exposure (FDA approval) ICD10: Z91.010-014, Z91.018 Z91.010 (peanuts), Z91.011 (milk), Z91.012 (eggs), Z91.013 (seafood), Z91.014 (mammalian meats), Z91.018 (other foods)	1. Request is obtained by an allergist or immunologist 2. Enrollee is at least one year of age 3. Enrollee has a confirmed diagnosis of IgE-mediated food allergy a. Must have documentation of a positive skin test or allergen-specific IgE blood test for each allergy within 12 months of the request b. Must have documentation of occurrence of significant allergic symptoms (moderate to severe skin, respiratory or gastrointestinal symptoms) when exposed to applicable allergens 4. Xolair is being used in conjunction with a food avoidant diet to the particular allergens 5. Pretreatment serum IgE levels must be provided on initial requests a. Coverage will be excluded for patients with an IgE of greater than or equal to 1850 IU/mL 6. Weight must be provide on initial and all continuation requests 7. Coadministration of Xolair or Omlyclo with a peanut protein desensitization therapy (Palforzia) or other oral immunotherapy has not been studied and will be considered experimental/investigational and will not be authorized. 8. Initial approval will be for 6 months. Continuation can be approved for 2 years and will require progress notes documenting that the member has had no severe allergic symptoms to food allergens while on Xolair or Omlyclo therapy AND that the member continues to practice food allergen avoidance.
Exclusion Criteria	
Xolair or Omlyclo will not be authorized in the following circumstances: a. Concurrent use with interleukin inhibitors (Dupixent, Nucala, Fasenra, Cinqair)	

b. Concurrent use with thymic stromal lymphopoietin (TSLP) inhibitors (Tezspire)
c. Concurrent use with peanut protein desensitization therapy (e.g., Palforzia) other oral immunotherapy (OIT)
d. Use for latex allergies, atopic dermatitis, or seasonal allergic rhinitis (hay fever)

Continuation Criteria

Continue current approval for Xolair or Omlyclo if following criteria are met.

- **For use in all indications:**
  - After initial approval period, requests will be reviewed every two years for clinical improvement or sustained efficacy.
- **For use in asthma:**
  - Improvement in asthma symptoms or asthma exacerbations is evidenced by decrease in one or more of the following:
    - Use of systemic corticosteroids
    - Two-fold or greater decrease in inhaled corticosteroid use for at least three days
    - Hospitalizations
    - ER visits
    - Unscheduled visits to healthcare provider
    - Improvement from baseline in forced expiratory volume in one second (FEV_1)
  - Approval will be contingent on the continued use of standard of care for asthma (inhaled corticosteroids and additional controlled medications such as long-acting beta-agonist inhalers). Xolair/Omlyclo is not FDA approved for monotherapy.
  - CDPHP expects that the use of Xolairtherapy will be part of a comprehensive asthma treatment regimen that includes, but is not limited to, intensive counseling on the importance of medication compliance and avoidance of allergic asthma triggers.

- **For use in urticaria: improvement is demonstrated by:**
  - Member demonstrate improvement in symptoms such as:
    - A decrease in the number and severity of hives and itching or increase in angioedema-free days
    - Decrease use of antihistamines

- **For CRSwNP-related requests:**
  - Member demonstrates improvement in symptoms of CRSwNP such as:
    - Reduction in nasal congestion
    - Reduction in rhinorrhea
    - Reduction in polyp size
    - Improvement in loss of smell
    - Reduction of facial pressure/pain or fullness
    - Reduction in oral corticosteroid use
  - Member continues to be adherent to intranasal corticosteroid

- **For IgE mediated food allergic reaction requests**:
  - Enrollee is continuing to demonstrate clinical benefit as assessed by the provider
  - Physician attests that the enrollee has not had anaphylaxis through accidental exposure where Xolair or Omlyclo is expected to exert an effect (dose limited exposure)

H2 antagonist	famotidine (Pepcid), cimetidine (Tagamet)

Considerations

- Prior authorization is obtained through the CDPHP pharmacy department
- Enrollee must have prescription drug coverage administered by CDPHP for medication obtained at a pharmacy
- Drugs listed above in the definition section may not be all-inclusive (last updated 9/24/2026).
- CDPHP reserves the right to make decisions based on clinical judgment on a case-by-case basis.
- CDPHP will not administer benefits for replacement doses of Xolair or Omlyclo due to the improper storage or reconstitution of this drug. It is the responsibility of the requesting practitioner to ensure that all medical staff are following the unique guidelines for the stability, storage, and reconstitution of Xolair or Omlyclo as indicated in the product insert for this drug.

GOVERNMENT PROGRAMS

CHILD HEALTH PLUS:	Subject to all terms and conditions noted in above application.
MEDICARE ADVANTAGE:	Refer to Medicare pharmacy policy: Xolair (Omalizumab).
SELECT PLAN/HARP:	Medical Benefit – Subject to all terms and conditions noted in above application. Pharmacy Benefit - Effective April 1, 2023, the pharmacy benefit for Medicaid is administered by NYRx, the Medicaid Pharmacy Program.

CDPHP Pharmacy Services 9/25/2026

New: 03/2017

Date	Notes
09/2018, 04/2020, 2/2021, 2/2022, 02/2023	Reviewed with no changes.
10/2017, 04/2019	Revised
2/2024	Background updated with 2023 GINA guidelines.
4/2024	Added new Indication of IgE mediated food allergic reactions.
6/2024	Revisions: Inclusion Criteria: Removed multiple food allergy requirement, specifically listed tree nut examples Continuation Criteria: Changed duration from six months to 12 months and removed continuation criteria involving Oral Food Challenge.
12/2024	Revised. Clinical criteria, exclusions, and continuation criteria all revised to align with other policies for medications used to treat the same indications to ensure consistency in the application of criteria.
6/2025	Revised. Added non-smoking requirement to asthma criteria. Added considerations for coverage when IgE levels are out of criteria range. Expanded duration of continuation approvals to 2 years.
12/2025	Defined IgE range for food allergy
9/2026	Renamed policy and added Omlyclo to policy

This Pharmacy Policy is the exclusive property of Capital District Physicians' Health Plan, Inc. (CDPHP®) and its affiliated companies, CDPHP Universal Benefits,® Inc. (CDPHP UBI) and Capital District Physicians' Healthcare Network, Inc. (CDPHN). The contents and form of this policy are proprietary to CDPHP. Any reproduction or replication of this policy without the express written permission of CDPHP, CDPHP UBI, and CDPHN is strictly prohibited. This policy is subject to contractual limitations and/or parameters established in any Employer sponsored Summary Plan Description (SPD) and/or Benefit Design Document (BDD).

Disclaimer Notice

The purpose of this policy is to provide guidance for benefit and coverage determinations only. Benefit and coverage determinations are subject to the contractual limitations of an enrollee's individual benefit plan.

If there is a discrepancy between this policy and an enrollee's individual benefit plan, the benefit plan will control. It is not the intent of this policy to dictate to health care practitioners how to provide appropriate health care to their patients. Health care practitioners shall exercise their own medical judgment when deciding the most appropriate care for enrollees. The CDPHP® coverage determinations are benefit decisions only and are not to be interpreted as providing health care services. CDPHP reserves the right to review this policy at any time and change it without notice.

Background

Spinal Muscular Atrophy (SMA) is a rare and irreversible neurodegenerative disease that affects the spinal cord, specifically the alpha motor neurons in the anterior horn.[1] As a result, SMA causes progressive proximal motor weakness and atrophy, in severe cases often resulting in early mortality. Critical muscle functions lost include walking, speaking, swallowing, and breathing, and the primary cause of death is respiratory muscle weakness leading to severe restrictive lung disease and progressive respiratory failure.[1]

SMA is linked to chromosome 5q and is recessive, caused by bi-allelic mutations in the SMN1 (Survival Motor Neuron 1) gene, which produces the SMN protein that is essential for motor neuron development. Specifically, the mutations include the homozygous deletion or deletion and mutation of the alleles of the SMN1 gene on chromosome 5q.[1-3] The SMN2 (Survival Motor Neuron 2) gene also produces SMN protein; however, only a small portion of the protein produced is functional. The number of SMN2 copies is important in determining the severity of SMA; however, those without SMN1 have an insufficient level of SMN protein regardless of the SMN2 copies. Prevalence is estimated at 1-2 per 100,000 persons, and incidence around 1 in 10,000 live births for SMA Type I accounting for 60% of all cases.[1]

There are five types of SMA based on age of onset and severity (Type 0-IV)[1-3]:
Type 0: This is the most severe subtype, which affects individuals in utero before birth and is very rare. These individuals often have joint contractures, respiratory distress and diffuse hypotonia (very low muscle tone) at birth and do not survive the neonatal period.
Type I (Infantile-onset SMA): This is the most common subtype of SMA (60% of cases) and has an age onset before six months where the highest achieved motor function includes sitting with support. The natural age of death is before two years without intervention, and there are typically 1-3 SMN2 copies.
Type II: This subtype has an onset from 6-18 months; children are able to sit but do not walk and survive into early adulthood, typically having 2-3 SMN2 copies.
Type III: This subtype has mild symptoms, comparatively, and has an onset of symptoms after 18 months of age. These individuals are able to walk independently; they may lose this ability in teens or later, but importantly, they are also able to survive into adulthood. There are typically 3-4 SMN2 copies present.
Type IV: This is the mildest subtype of the condition, with the onset of symptoms occurring as an adult and progressing very slowly. Individuals are able to stand and walk, and usually have normal lifespans. There are typically at least 4 SMN2 copies present in this subtype.

Clinical Classification of Spinal Muscular Atrophy (SMA)[5]

Type	Age of onset	Requires respiratory support at birth	Able to sit	Able to stand	Able to walk	Life expectancy	Predicted SMN2 copy number
0	Prenatal	Yes	No	No	No	< 6 months	1
1	< 6 months	No	No	No	No	< 2 years	2
2	6 to 18 months	No	Yes	No	No	10 to 40 years	3
3	> 18 months	No	Yes	Yes	Assisted	Adult	3 to 4
4	> 5 years	No	Yes	Yes	Yes	Adult	> 4

Zolgensma is an adeno-associated virus serotype 9 vector that delivers a copy of SMN to supplement the defective SMN1 gene.[2,4] This is a fully functional human SMN under control of a continuous promoter, which is designed to boost levels of SMN protein in a rapid and sustainable way.

Zolgensma has been studied in a Phase I open-label, two-cohort trial and an extension study (START) in infantile onset (Type 1 SMA).[3] Subjects in the open-label, single-arm clinical trial experienced an onset of clinical symptoms consistent with SMA prior to six months of age and had genetically confirmed bi-allelic SMN1 gene deletions alongside 2 copies of the SMN2 gene. The 12 *therapeutic dose* trial subjects also had absence of the c.859G>C modification in exon 7, which predicts a milder phenotype. Lastly, these individuals had a negative baseline anti-AAV9 antibody titer (< 1:50) and were less than six months of age by the time they received the Zolgensma infusion. Baseline

characteristics included a mean age of diagnosis of 8.6 weeks, with age at onset of 1.4 months.[3] The mean CHOP-INTEND (Children's Hospital of Philadelphia-Infant Test of Neuromuscular Disorders) score was 28 (range 12-50).[3] After treatment with Zolgensma, all infants were alive and even-free (death or permanent ventilation) through 24 months.[3] Motor milestones reached by the subjects included head control (n-11), rolling over (n-9), sitting unassisted (n-10), and feeding orally as well as speaking (n-11), and finally 2 subjects were able to walk independently.[3] The safety elements identified in this trial included two subjects having an elevation in serum aminotransferase following infusion; these were grade 4AEs, and oral prednisolone treatment was added as pre- and post- treatment to Zolgensma therapy following the first infant's liver function elevation.[3] Another Phase 3 trial, Gene Replacement Therapy Clinical Trial for Patients With Spinal Muscular Atrophy Type 1 (STR1VE), studied symptomatic children from less than six months of age with SMA Type 1 and 1-2 copies of SMN2.[2] The STR1VE trial showed that Zolgensma significantly increased event-free survival in these patients when compared to natural history patients (91% of patients were alive and free of permanent ventilation at the 14-months-of-age study visit).[6] The trial also showed 59% of Zolgensma-treated patients were able to sit without support for ≥ 30 seconds at the 18-month-of-age study visit. Another Phase 3 trial, Pre-Symptomatic Study of Intravenous AVXS-101 in Spinal Muscular Atrophy (SMA) for Patients with Multiple Copies of SMN2 (SPR1NT), investigated the use of Zolgensma in those that are considered pre-symptomatic with SMA alongside 2 or 3 copies of SMN2.[2] All 14 patients enrolled in the trial were able to sit without support for ≥ 30 seconds up to the 18-months-of-age visit.[7]

Itvisma (onasemnogene abeparvovec-brve) is an adeno-associated virus vector-based gene therapy indicated for the treatment of spinal muscular atrophy (SMA) in adult and pediatric patients 2 years of age and older with a confirmed mutation in the survival motor neuron 1 (SMN1) gene.

Summary	
Effective Date of Policy:	4/7/2026
ICD10 Diagnosis Codes	G12.0, G12.1, G12.9
Availability	Zolgensma: Customized kit to meet dosing requirements for each patient Itvisma: single-dose vial with an extractable volume of not less than 3 mL, containing 1.2×10^{14} vg
HCPCS Code	Zolgensma: J3399 Itvisma: no specific code (J3590)
Approval duration	Zolgensma: 3 months to allow for the administration of the one-time treatment or until 2 years of age, whichever occurs first Itvisma: 3 months to allow for the administration of the one-time treatment

Required Criteria for Initial Approval

All of the following conditions for the requested indication must be met in order to approve Zolgensma:

Product	Inclusion	Recommended Dosing Regimen

Zolgensma (onasemnogene abeparvovec-xioi)	• Prescribed by, or in consultation with, a provider who specializes in the diagnosis and management of spinal muscular atrophy (SMA) and/or neuromuscular disorders
	• Enrollee is less than two years of age and weighs ≤ 21 kg
	  o For neonatal patients born prematurely, term gestational age (37 weeks) must be reached
	• Enrollee has a diagnosis of spinal muscular atrophy confirmed by:
	  o Genetic demonstration of bi-allelic SMN1 gene deletion or mutation:
	  ▪ Homozygous deletions of SMN1 gene OR
	  ▪ Homozygous mutation in the SMN1 gene (e.g., biallelic mutations of exon 7) OR
	  ▪ Compound heterozygous mutation in the SMN1 gene (e.g., deletion of SMN1 exon 7 and mutation of SMN1)
	• Must have genetic testing confirming 1, 2, 3, or 4 copies of the SMN2 gene
	• Enrollee must have baseline anti-AAV9 antibody titers of ≤ 1:50 (e.g., anti-AAV9 antibody titers of ≤ 1:25)
		• One lifetime administration of Zolgensma
		• Dosage should not exceed 1.1×10^{14} vector genomes (vg) per kg of body weight administered as an IV infusion over 60 minutes. Systemic corticosteroids (equivalent to oral prednisolone at 1mg/kg of body weight) must be administered starting one day prior to Zolgensma infusion and continuing for a total of 30 days
		• Refer to the prescribing information for the determination of the appropriate dose volume that corresponds to the patient's weight. Coverage will be limited to one customized Zolgensma kit that meets these dosage requirements

	• Clinical documentation supports that the enrollee does NOT have advanced SMA at baseline (i.e., complete paralysis of limbs OR permanent ventilator dependence)
	  o Permanent ventilator support defined as ventilator assistance for ≥ 16 hours/day for at least 14 days without an acute, reversible illness
	• Enrollee will not be concurrently receiving either Spinraza (nusinersen) or Evrysdi (risdiplam) or any other experimental therapy for spinal muscular atrophy with Zolgensma
	  o Member's medical record will be reviewed and any current Spinraza or Evrysdi approval will be terminated upon Zolgensma approval
	• Must not have previously received any gene therapy, including either formulation of onasemnogene abeparvovec or any other AAV9- or SMN1-directed gene-replacement therapy (including investigational treatments). This exclusion applies regardless of route of administration of prior therapy as antibody response is systemic.	

Itvisma (onasemnogene abeparvovec-brve)	1. Must be prescribed by, or in consultation with, a provider who specializes in the treatment of Spinal Muscular Atrophy (SMA) and/or neuromuscular disorders AND
	2. Must be between ≥ 2 years and < 18 years of age AND
	3. Must have a genetically confirmed diagnosis of Spinal Muscular Atrophy (SMA), supported by documentation of:
	  a. Biallelic SMN1 deletion or mutation confirmed by molecular genetic testing (homozygous deletion, homozygous mutation, or compound heterozygous mutation) AND
	  b. Genetic testing confirming 2, 3, or 4 copies of the SMN2 gene AND
	4. Must have a clinical presentation consistent with SMA Type 2 or non-ambulatory SMA Type 3, characterized by:
	  a. Absence of sustained independent ambulation at the time of the request OR documented loss of independent ambulation within the prior 12 months AND
	  b. Evidence of preserved motor neuron reserve, demonstrated by:
	  i. Ability to sit independently without external support (e.g., without a caregiver assisting, without positioning devices) OR
	  ii. Preserved antigravity upper-limb function on clinical examination or standardized assessment (e.g., RULM) AND
	  c. Must have objective evidence of disease progression, demonstrated by documentation of
	  i. A decline in standardized motor function assessments, (e.g., HFMS-E, RULM, or equivalent) within the prior 12 -months OR
		• Itvisma must be dosed and administered per the FDA-approved prescribing information which includes:
		• Single-dose intrathecal injection of 1.2×10^{14} vector genomes (vg) via lumbar puncture
		• Required corticosteroid regimen (prednisolone 1 mg/kg/day beginning one day prior to injection, continued for 30 days, followed by gradual taper)
		• Post-treatment monitoring of liver function and platelet counts as specified in the prescribing information

	ii. A loss of motor milestones within the prior 12-motnths 5. Must have a current (within 30 days prior to treatment) anti-AAV9 neutralizing antibody titer at or below the laboratory's validated cutoff (typically ≤ 1:50; some validated assays use ≤ 1:25) a. Laboratory report must specify assay type, date, and threshold AND 6. Vaccination and Infection Precautions a. Must have no active infection at the time of treatment; patient must be clinically stable b. Must have no live-attenuated vaccine (e.g., MMR, varicella, zoster) within 30 days before or 2 months after treatment c. Must have documentation of varicella immunity (IgG positive or prior vaccination) must be submitted AND 7. Documentation must confirm that the patient does not have any contraindication to lumbar puncture, including: a. Increased intracranial pressure due to mass lesion or hydrocephalus; b. Coagulopathy (INR > 1.4 or platelets < 100,000/μL) or current anticoagulant use; c. Local infection at the puncture site or systemic sepsis; d. Severe spinal deformity, fusion, or hardware precluding safe LP access; AND 8. Must have baseline laboratory assessment (within 7 days prior to treatment) a. AST, ALT, total bilirubin, PT/INR b. CBC with platelets c. BUN/creatinine d. LDH and haptoglobin e. Blood pressure f. Varicella IgG	

Exclusion Criteria

Zolgensma will not be authorized if **any** of the following criteria are met:

- Retreatment with Zolgensma has not been proven to be safe and effective and will be considered experiment/investigational. This includes patients who received a partial or incomplete dose of Zolgensma.

Itvisma will not be authorized if any of the following criteria are met:

- Enrollee has any of the following:
  - Significant hepatic impairment (AST/ALT > 5× ULN or bilirubin > 2× ULN);
  - Active infection or febrile illness within 30 days;
  - Uncorrected coagulopathy or thrombocytopenia;
  - Contraindication to lumbar puncture (see Section 6);
  - Ventilator dependence or end-stage SMA (complete paralysis of limbs, permanent ventilator use);
  - Recent major surgery or pulmonary decompensation (< 2 months);
  - Active varicella or herpes zoster infection;
  - Prior treatment with any AAV-based or other viral-vector gene therapy.
- Patients with advanced SMA (i.e., complete paralysis of limbs, permanent ventilator dependence) will be excluded from treatment due to lack of literature support

- Permanent ventilation is defined as requiring invasive ventilation (tracheostomy), or invasive/noninvasive respiratory assistance for ≥ 16 hours daily for ≥ 14 days in the absence of an acute reversible illness and excluding perioperative ventilation

- For SMA treatment experienced patients:
  - If previously treated with nusinersen (Spinraza), the patient must have received their last dose of nusinersen ≥ 4 months
  - If previously treated with risdiplam (Evrysdi), the patient must have received their last dose of risdiplam ≥ 15 days prior
- Itvisma will not be approved for use in combination with Spinraza or Evrysdi or any other experimental therapy for spinal muscular atrophy
- Must not have previously received any gene therapy, including either formulation of onasemnogene abeparvovec or any other AAV9- or SMN1-directed gene-replacement therapy (including investigational treatments). This exclusion applies regardless of route of administration of prior therapy as antibody response is systemic.
- Retreatment with Itvisma has not been proven to be safe and effective and will be considered experiment/investigational. This includes patients who received a partial or incomplete dose of Itvisma.

Continuation Criteria

- Not applicable; therapy is authorized only for one lifetime administration of Zolgensma

Considerations

- Physician acknowledges that CDPHP will request documentation, not more frequently than biannually, of follow-up patient assessments including serial CHOP INTEND (Children's Hospital of Philadelphia Infant Test of Neuromuscular Disorders) or HFMSE (Hammersmith Functional Motor Scale Expanded) assessments while the patient is under the care of the physician
- Systemic corticosteroids should be administered to all enrollees before and after Zolgensma infusion[4]
- Enrollees receiving Zolgensma therapy should have liver function monitored for at least three months after receiving therapy, at intervals of weekly for the first month, followed by every other week for months two and three, until results are unremarkable.
- Enrollees receiving Zolgensma therapy should have troponin-I monitored before infusion and on a regular basis after infusion (weekly for the first month, and then monthly for the second and third months) until troponin-I levels return to baseline[4]
- Prior authorization is obtained through the CDPHP pharmacy department

CDPHP Pharmacy Services 4/6/2026

New: 8/2019

Revised	Reviewed
9/20, 9/22, 9/23, 9/25, 4/26	9/2021, 9/2024

Revision Date	Changes Made
09/2022	Added SMA classification criteria table, updated clinical trial results, added systemic corticosteroid consideration, added troponin-I monitoring consideration
9/2023	Added to inclusion criteria statement excluding concomitant nusinersen or risdiplam treatment following Zolgensma administration
9/2025	Updated approval duration
4/2026	Renamed policy from Zolgensma (onasemnogene abeparvovec-xioi) Added Itvisma Updated number of copies of SMN2 gene for Zolgensma Removed labs for Zolgensma

Background

Thalassemias are inherited hemoglobinopathies in which impaired production of one type of globin chain; either alpha or beta, causes an imbalance in the ratio between those chains. These chains precipitate and cause significant cellular damage, thus causing issues with red blood cell maturation and leads to ineffective erythropoiesis, hemolytic anemia, iron overload, and ensuing complications. Specifically in beta-thalassemia, this impaired production is caused by mutations in the hemoglobin beta globin gene. There are more than 350 beta-thalassemia mutations currently known, and while distinction of the various phenotypes of thalassemia is mostly based on clinical parameters, genotype-phenotype associations are commonly established. There are four different phenotypes in beta-thalassemia: Major, intermedia, trait/minor, and silent carriers. However, in terms of treatment, individuals with beta thalassemia are classified as either being transfusion dependent (TDT) or non-transfusion dependent (NTDT).

Transfusion dependent individuals are those patients that require regular, life-long transfusions to mitigate severe anemia and extramedullary hematopoiesis. This classification does not include those patients who only periodically require transfusions for anemia, but they may become fully transfusion dependent over time. Non-transfusion dependent individuals do not require regular transfusions.

Whichever the category a patient falls into, the management of beta thalassemia mainly involves treating the anemia if it is severe enough to cause symptoms, reducing ineffective erythropoiesis, preventing excess iron stores from forming, and treating the complications of such iron overload if it occurs. Both TDT and NTDT are fluid categories based on clinical parameters, and a patient can switch from one group to the other over the course of their lives. As such, these designations should primarily represent a patient's current clinical status.

If iron overload occurs from the frequent transfusions, it can cause organ toxicity and potentially mortality. In this case, it may be necessary to use iron chelation therapy to remove excess iron from the body. Currently, there are three iron chelating agents on the market for iron overload: deferasirox, deferiprone, and deferoxamine. No single agent is considered the "gold standard," and long-term randomized, prospective studies for this comparison are lacking. However, all three are approved for the treatment of iron overload in transfusion-dependent thalassemia, and the choice of agent is largely dependent on preference of the prescriber and patient, patient age, comorbidities, and side effect profile.

Transfusion-dependent patients will also have ineffective erythropoiesis. If this is the case, then the patient can be prescribed an activin receptor ligan trap. The only drug currently on the market is luspatercept, approved for use in 2019 and indicated for the treatment of adult patients with beta thalassemia who require regular red blood cell (RBC) infusions. In these patients who require regular transfusions, luspatercept can serve to reduce the number of transfusions a patient may need, but individuals who are tolerating regular transfusions may continue to stay on just transfusion therapy. Other patients may seek curative treatment with hematopoietic stem cell transplant (which, due to complications such as graft-versus-host-disease, is only recommended in young children with an HLA-identical sibling) or gene therapy. The primary evidence for efficacy of luspatercept comes from the BELIEVE trial, which showed that compared to placebo, luspatercept was able to significantly increase hemoglobin levels and reduce the number of transfusions participants needed to receive. This can reduce a patient's transfusion burden and maintain quality of life. Patients who may qualify for luspatercept may also benefit from undergoing a splenectomy, however splenectomy is associated with a variety of adverse outcomes in patients, namely hypercoagulable states. Considering that undergoing splenectomy may not eliminate the need for other therapy, and its adverse effects, splenectomy is best reserved for certain patients.

Until now, the only curative treatment for beta-thalassemia was hemopoietic stem cell transplant from an HLA-matched donor. Zynteglo (betibeglogene autotemcel (beti-cel)) was approved in August 2022 as an autologous hematopoietic stem cell-based gene therapy indicated for the treatment of adult and pediatric patients with β-thalassemia who require regular red blood cell (RBC) transfusions. Zynteglo is intended to be a one-time gene therapy product administered as a single dose. Zynteglo works by adding functional copies of a modified form of the beta-globin gene (βA-T87Q-globin gene) into a patient's own hematopoietic (blood) stem cells (HSCs) in the ex vivo setting, and the HSCs are then administered via a onetime hospital inpatient infusion.

The approval of Zynteglo is based on data from the single-arm, open-label, Phase 3 HGB-207 (Northstar-2) and HGB-212 (Northstar-3) trials and the long-term follow-up study, LTF-303. The Phase 3 trials included 41 patients between 4 and 34 years of age with both non-β0 /β0 and β0 /β0 genotypes. Of the evaluable patients, 89% (32/36) achieved transfusion independence (TI), which is defined as no longer needing RBC transfusions for at least 12 months while maintaining a weighted average total hemoglobin level of at least 9 g/dL.

Policy/Procedure Name: Zynteglo (Betibeglogene autotemcel) **Control Number:** 1350/20.000451

Summary	
Effective Date of Policy:	2/12/2026
Indications	Transfusion Dependent Beta Thalassemia (TDT)
ICD10 Diagnosis Codes	D56.1
HCPCS Code	J3393
Availability	*Per FDA Prescribing Information*
Duration	Authorization will be for 6 months to allow sufficient time for administration

Required Criteria for Initial Approval

All of the following conditions for the requested indication must be met in order to approve therapy:

Specific Indication	Inclusion Criteria	Recommended Dosing

Indication
Transfusion Dependent Beta Thalassemia
ICD10: D56.1
	• Enrollee is between four and 50 years of age
	  ○ If enrollee is less than five years of age they must weigh ≥ 6 kilograms and be expected to provide the minimum number of cells to initiate the therapeutic manufacturing process
	• Therapy is prescribed by or in consultation with a hematologist
	• Enrollee has diagnosis of Transfusion Dependent Beta Thalassemia with genetic confirmation of the following:
	  ○ Non-β0/β0 genotype (i.e., β0/β+, βE/β0, and β+/β+) OR
	  ○ β0/β0 genotype (other examples include: β0/β+(IVS-I-110) and β+(IVS-I-110)/β+(IVS-I-110))
	• Enrollee has had regular peripheral blood transfusions to maintain target hemoglobin levels
	• Enrollee has been treated and followed for at least the past two years in a specialized center that maintained detailed medical records, including transfusion history
	• Clinical documentation supports the enrollee has had the following in the previous two years (one of the below two options):
	  ○ Receipt of ≥ 8 transfusions of packed red blood cells (pRBC) per year OR
	  ○ Receipt of ≥ 100 mL/kg/year of pRBC per year
	• Karnofsky performance status of ≥80 for adults (≥16 years of age) or a Lansky performance status of ≥80 for adolescents (<16 years of age)
	• Negative serologic test for HIV infection (as per US FDA prescribing label, apheresis material from individuals with a positive test for HIV will not be accepted for betibeglogene autotemcel manufacturing).
		• Per FDA Prescribing Information

Exclusion Criteria

Therapy will not be covered if any of the above noted Inclusion Criteria are NOT met OR any of the below noted Exclusion Criteria are met:

- Presence of HBB mutations other than what is specifically noted in the above Inclusion Criteria
- Enrollee has received a HSCT or Gene therapy previously in their lifetime
- Enrollee has a known and available HLA-matched family donor willing to participate in an allogeneic HSCT
- Enrollee is ineligible for HSCT (separate from points in above Exclusion Criteria)
- Contraindication to the use of granulocyte colony stimulating factor (G-CSF), plerixafor, busulfan, or any other medicinal products required during myeloablative conditioning, including hypersensitivity to the active substances or to any of the excipients.
- White Blood Cell (WBC) count < 3×10^9/L
- Platelet count < 100×10^9/L (not related to hypersplenism)
- Uncorrected bleeding disorder
- Any prior or current malignancy (with the exception of adequately treated cone biopsied in situ carcinoma of the cervix uteri and basal or squamous cell carcinoma of the skin) or myeloproliferative or significant immunodeficiency disorder

- Any immediate family member (i.e., parent or siblings) with a known Familial Cancer Syndrome (including but not limited to hereditary breast and ovarian cancer syndrome, hereditary nonpolyposis colorectal cancer syndrome and familial adenomatous polyposis)
- Evidence of advanced liver disease (meets any of the following):
    - Persistent aspartate transaminase, alanine transaminase, or direct bilirubin value greater than 3 times the upper limit of normal.
    - Baseline prothrombin time or partial thromboplastin time greater than 1.5 times the upper limit of normal.
    - Magnetic resonance imaging of the liver demonstrating clear evidence of cirrhosis.
    - Liver biopsy demonstrating cirrhosis, any evidence of bridging fibrosis, or active hepatitis
- T2*-weighted magnetic resonance imaging measurement of myocardial iron of less than 10 msec or other evidence of severe iron overload in the opinion of treating physician.
- Baseline estimated glomerular filtration rate less than 70 mL/min/1.73 m^2
- Active, uncontrolled HCV or HBV infection

Continuation Criteria

Continuation criteria is not applicable, this is a one-time lifetime treatment only and therefore repeat administration will not be covered.

Considerations

- Prior authorization is obtained through the CDPHP pharmacy department.
- Zynteglo (betibeglogene autotemcel) is considered investigational when the above criteria are not met
- Zynteglo (betibeglogene autotemcel) is considered investigational for all other indications
- Retreatment with Zynteglo (betibeglogene autotemcel) will be considered investigational when FDA approved gene therapy, or any other gene therapy under investigation, has been previously administered

GOVERNMENT PROGRAMS

CHILD HEALTH PLUS:	Subject to all terms and conditions noted in above application.
MEDICARE CHOICES:	Subject to all terms and conditions noted in above application.
SELECT/HARP PLAN:	Refer to MEDICAID - Zynteglo (Betibeglogene autotemcel) policy 1350/20.000489. Zynteglo (betibeglogene autotemcel) is reimbursed by Medicaid fee-for-service pharmacy program for Medicaid Managed Care Members

CDPHP Pharmacy Services 2/12/2026

New: 6/2022

Revised	Reviewed
12/2022, 9/2024, 4/2025, 2/2026	

Revision Date	Changes Made
12/2022	Changed title of Policy from Betibeglogene autotemcel (beti-cel) to Zynteglo (Betibeglogene autotemcel) Updated Select/HARP applicability to reflect that BlueBird is not participating in the MDRP and therefore not eligible for coverage.
12/2022	Changed Applicability to include Select/HARP plan.
9/2024	Updated background, Inclusion Criteria Revisions: Clarified prescriber requirement to include consultation of hematologist; Added non-β0/β0 mutation; Reduced transfusion requirement - receipt of ≥ 8 transfusions of packed red blood cells (pRBC) per year (previously 11 transfusions)
2/2026	Updated authorization will be for 6 months to allow sufficient time for administration Updated youngest age from 5 years of age to 4 years of age Added Karnofsky performance score and negative HIV test Updated exclusion criteria Removed duplicative criteria from inclusion criteria that was already encompassed in exclusion criteria Removed Enrollee has been treated and followed for at least the past two years in a specialized center that maintained detailed medical records, including transfusion history Clarified mutations Updated iron overload exclusion criteria
